On the Generating Functionals of a Class of Random Packing Point Processes

Tien Viet Nguyen^{*} and François Baccelli[†]

November 20, 2013

Abstract

Consider a symmetrical conflict relationship between the points of a point process. The Matérn type constructions provide a generic way of selecting a subset of this point process which is conflict-free. The simplest one consists in keeping only conflict-free points. There is however a wide class of Matérn type processes based on more elaborate selection rules and providing larger sets of selected points. The general idea being that if a point is discarded because of a given conflict, there is no need to discard other points with which it is also in conflict. The ultimate selection rule within this class is the so called Random Sequential Adsorption, where the cardinality of the sequence of conflicts allowing one to decide whether a given point is selected is *not* bounded. The present paper provides a sufficient condition on the span of the conflict relationship under which all the above point processes are well defined when the initial point process is Poisson. It then establishes, still in the Poisson case, a set of differential equations satisfied by the probability generating functionals of these Matérn type point processes. Integral equations are also given for the Palm distributions.

1 Introduction

This paper is concerned with systems ϕ made of a collection of points in \mathbb{R}^d , where points are equipped with a pairwise *conflict relation*. As an example, one can think of the locations of dominant male lions in a region. These lions compete with each other for resources, so that they do not like to be too close to each other. Hence, it makes sense to say that there is a conflict between two points representing the locations of two such lions if the distance between them is, say, smaller some distance d .

These questions play an important role in physics, chemistry, material science, etc., where they have been used to describe systems with hard-core interactions such as reactions on polymer chains [8], chemisorption on a single-crystal

^{*}Qualcomm, USA

[†]UT Austin, USA and INRIA, France

surface [7] and adsorption in colloidal [15] systems. In these problems, each object in the system occupies some space, and two points with overlapping occupied space have a conflict. Problems of this type also arise in forestry [9] and in wireless communications [3].

The paper is centered on what happens after conflicts are resolved (e.g. once, for all pairs of conflicting lions, one has eliminated the other). More precisely, we focus our attention on the three classical constructions of *conflict-free subsets* ϕ_j ($j = \text{I, II, III}$) of ϕ which were proposed by Matérn [10] and which are described below.

The setting will be that where the locations of points and the conflict relations are random. The conflict system will hence be a random point process (PP) equipped with a random conflict relation. The Matérn constructions then lead to a family of PPs Φ_j ($j = 1, 2, \dots, \infty$), which are almost surely (a.s.) conflict-free when j is either even or equal to ∞ .

The paper is structured as follows. The models are introduced in Section 3. The existence issue is discussed in Section 4. The dynamical view point on these processes, which is instrumental to establish the differential equations, is introduced in Section 5. The differential equations satisfied by the generating functionals are established in Section 6, and in Section 7 for the Palm case.

2 State of the Art and Contributions

In dimension 1, the first model of this kind is the car parking model which was independently studied by A. Rényi [13] and by H. Dvoretzky and A. Robbins [6]. In this model, cars of fixed length are parked in the same manner as in the ∞ -Matérn model (see below). Consider an observation window $[0, x]$ and let $N(x)$ be the number of cars parked in this window when there is an infinite number of cars to be parked (saturated regime). A. Rényi showed that $N(x)$ satisfies the law of large number (LLN):

$$\lim_{x \rightarrow \infty} \frac{N(x)}{x} = C \approx 0.74759 \text{ a.s. ,}$$

where C is called the packing density. H. Dvoretzky and A. Robbins [6] sharpened this result to a central limit theorem (CLT):

$$\frac{N(x) - Cx}{\text{Var}(N(x))} \rightarrow \mathcal{N}(0, 1) \text{ in distribution as } x \rightarrow \infty.$$

Various extensions of the above models were considered like the non-saturated regime (the number of cars to be parked is finite), random car lengths, etc. [11, 4]. The latter is also known under the name random interval packing and has many applications in resource allocation in communication theory. For the above models, the obtained results concern the packing density, the LLN, the CLT, the distribution of packed intervals and that of vacant intervals.

For dimension more than 1, the most noticeable advance in this field is a series of papers by M.D. Penrose, J.E. Yukich and Y. Baryshnikov. Based on

a general LLN and CLT for *stabilizing* functionals, the LLN and CLT were established for the n dimensional RSA model in the non-saturated [12] regime. Y. Baryshnikov and J. E. Yukich [2] later strengthened the above results by proving that, in the thermodynamic limit, the spatial distribution of the p.p. induced by the RSA model converges to that of a Gaussian field after a suitable rescaling in the non-saturated regime. The LLN and CLT for the n dimensional RSA model in the saturated regime was proven by T. Schreiber *et al* [14].

In general, characterizing the distribution of the point processes induced by these models beyond first and second moment measures is still an open problem. The results in this paper shed some light on this characterization. The contributions are twofold: we first give conditions under which each Φ_j is well defined; under these conditions, we then characterize its probability generating functional (p.g.fl) as the unique solution of a system of functional differential equations. Using the relation between the Palm and non-Palm distribution of a PP, we also show that the p.g.fl of Φ_j under its Palm distributions satisfies a related system of integral equations. To the best of our knowledge, these systems of equations are new.

3 Matérn's Constructions and Extensions

Let c be a symmetric, non-reflexive, $\{0, 1\}$ -valued relation between the points of ϕ . For any x and y in ϕ , $c(x, y) = 1$ means that x and y conflict with each other.

The *Matérn type I construction* builds the conflict-free system ϕ_I by removing from ϕ all objects which conflict with at least another object in ϕ . In other words,

$$\phi_I = \{x \in \phi \text{ s.t. for all other } y \in \phi, c(x, y) = 0\}. \quad (3.1)$$

For convenience, we refer to a construction of the last type as a *conflict resolution mechanism*. It is important to bear in mind that this mechanism is not the only one that produces a conflict-free system. Another example of conflict resolution mechanisms is the time-based conflict resolution mechanism used in the Matérn type II model.

The *Matérn type II construction* gives each point x a mark $t(x)$ which takes value in $[0, 1]$ as an additional attribute of point x . This mark is interpreted as the time when the point 'arrives' in the system. For convenience, we refer to this mark as the timer of the point. The spatial conflict between two points is resolved by a competition where whichever arrives first wins. Only the winning points belong to ϕ_{II} , i.e.

$$\phi_{II} = \{x \in \phi \text{ s.t. for all } y \in \phi, c(x, y) = 1 \Rightarrow t(x) < t(y)\}. \quad (3.2)$$

In the literature this construction is sometimes referred to as the Matérn hard-core model.

The *Matérn type III construction* is proposed with the purpose of resolving conflicts while retaining as many points as possible. In this sense, it can be

viewed as an improvement of the Matérn type II model. The intuition behind this mechanism is as follows: when an object competes with others for space, it does not need to compete with those objects that have already been defeated. When the system ϕ contains only finitely many objects, we can give an explicit construction for the system ϕ_{III} . First, all the objects in ϕ are sorted in the increasing order of the values of their timers. Let $\{x_i, i = 1, 2, \dots\}$ be this ordering. We then construct an increasing sequence of sets $\{\phi_{\text{III}}^{(i)}, i = 1, 2, \dots\}$ as follows.

$$\begin{aligned}\phi_{\text{III}}^{(1)} &= \{x_1\}; \\ \phi_{\text{III}}^{(i+1)} &= \begin{cases} \phi_{\text{III}}^{(i)} \cup \{x_{i+1}\} & \text{if } c(x_{i+1}, x_j) = 0 \text{ for all } x_j \in \phi_{\text{III}}^{(i)}, \\ \phi_{\text{III}}^{(i)} & \text{otherwise.} \end{cases}\end{aligned}$$

The system ϕ_{III} is defined as $\bigcup_{i=1}^{\infty} \phi_{\text{III}}^{(i)}$. It is easily seen that ϕ_{III} satisfies:

$$\phi_{\text{III}} = \{x \in \phi \text{ s.t. for all } y \in \phi_{\text{III}}, c(x, y) = 0 \Rightarrow t(x) < t(y)\}. \quad (3.3)$$

In applications in physics, chemistry and material science, the Matérn type III model is sometimes referred to as the Random Sequential Adsorption (RSA) model (see [12] and the citations herein).

When ϕ contains infinitely many objects, there are configurations of ϕ such that the type III construction is not applicable. A simple example is the case where objects in ϕ are located at points in \mathbb{Z}^+ and $t(i) = i^{-1}$. We can easily see that there is no way to sort the objects in ϕ in the increasing order of their timers. Nevertheless, the construction of Matérn type III model can still be extended to the case where $|\phi| = \infty$ under some mild condition. This construction is more involved and we postpone its discussion to Section 4.

Having recalled the classical constructions of the Matérn models of type I, II and III, we can now introduce our extensions. As shown in Subsection 4.2, these extensions form a bridge between Matérn type II and Matérn type III models.

1. *The 0-Matérn and the 1-Matérn constructions* produce ϕ_0, ϕ_1 which are the original system ϕ and the system ϕ_{II} produced by the Matérn type II model respectively.
2. *The 2-Matérn construction* produces a subset ϕ_2 of ϕ from ϕ_1 in the following fashion. Each object x in ϕ identifies in ϕ_1 a set $A(x)$ of objects having a conflict with it. It is included in ϕ_2 if it wins all the competitions with the elements of $A(x)$. In other words,

$$\begin{aligned}A(x) &:= \{y \in \phi_1 \text{ s.t. } c(x, y) = 1\}; \\ \phi_2 &:= \{x \in \phi \text{ s.t. for all } y \in A(x), t(x) < t(y)\} \\ &= \{x \in \phi \text{ s.t. for all } y \in \phi_1, c(x, y) = 1 \Rightarrow t(x) < t(y)\}. \quad (3.4)\end{aligned}$$

3. *The $(k + 1)$ -Matérn construction* is recursively constructed from the k -Matérn model in the same manner as the 2-Matérn model is constructed

from the 1-Matérn model, i.e.

$$\phi_{k+1} := \{x \in \phi \text{ s.t. for all } y \in \phi_k, c(x, y) = 1 \Rightarrow t(x) < t(y)\}. \quad (3.5)$$

As a final note for this section, we want to stress that while Matérn used timers taking values in $[0, 1]$ (or more generally, in any bounded interval) in his construction, it is sometimes more convenient to have timers taking values in \mathbb{R}^+ . This is in particular the case in Section 6 where this extension allows us to obtain simpler analytical results. Hence, from now on we adopt this extension.

4 The Extended Matérn Type III Construction

Our aims here are to provide an extension of the Matérn type III construction to the case where ϕ contains countably many points and to prove that the subset ϕ_∞ produced by this construction is a suitably defined *limit* of the sets ϕ_k when k goes to infinity. We start by defining the *conflict graph* associated with ϕ and c . Then we give our extension which is applicable only when the conflict graph has the *finite history* property. The conflict graph and the finite history property are defined in Subsection 4.1. We close this section by proving that when the later condition is satisfied, we have $\phi_\infty(\phi, t, c) = \bigcup_{k=0}^{\infty} \phi_{2k+1} = \bigcap_{k=0}^{\infty} \phi_{2k}$. For this reason, we refer to the construction in this section as the ∞ -Matérn model.

4.1 Conflict Graph and ∞ -Matérn Model

For any two points x and y in ϕ , we put a directed edge from x to y if $c(x, y) = 1$ and $t(x) < t(y)$. Let \mathcal{E} be the set of all such edges

$$\mathcal{E} = \{(x, y) \in \phi^2 \text{ s.t. } c(x, y) = 1 \text{ and } t(x) < t(y)\}.$$

The *conflict graph* associated with ϕ and c is the directed graph $\mathcal{G} = \{\phi, \mathcal{E}\}$. It is not difficult to check that \mathcal{G} is an acyclic graph.

We can now recursively define the order (i.e. an asymmetric, transitive binary relation) \leftarrow of ϕ as

$$x \leftarrow y \text{ if } \begin{cases} \text{either } (x, y) \in \mathcal{E}, \\ \text{or there exists } z \in \phi \text{ s.t. } (z, y) \in \mathcal{E} \text{ and } x \leftarrow z. \end{cases} \quad (4.1)$$

We call this the *ancestor* order in ϕ . For each x , let

$$\mathcal{A}(x) = \{y \in \phi \text{ s.t. } y \leftarrow x\}, \quad (4.2)$$

be the set of its *ancestors*. \mathcal{G} is said to have the *finite history* property if $\mathcal{A}(x)$ is finite for all x in ϕ .

When \mathcal{G} has the finite history property, let e_∞ (the ∞ subscript is explained in Subsection 4.2) be a $\{0, 1\}$ -value function taking elements of ϕ as argument

and satisfies:

$$e_\infty(x) = \begin{cases} 1 & \text{if } \mathcal{A}(x) = \emptyset, \\ \prod_{y \in \phi, (y,x) \in \mathcal{E}} (1 - e_\infty(y)) & \text{otherwise .} \end{cases} \quad (4.3)$$

We have then,

Proposition 1 *When the conflict graph \mathcal{G} has the finite history property, there exists a unique function e_∞ satisfying (4.3).*

Proof. It is sufficient to show that $e_\infty(x)$ is uniquely determined for every x in ϕ . We do this by induction on $|\mathcal{A}(x)|$, this is possible by the finite history property assumption (so that $|\mathcal{A}(x)| < \infty$ a.s.). The base case is when $|\mathcal{A}(x)| = 0$ so that $e_\infty(x) = 1$ by definition. Note that such a x always exists by the finite history assumption (the argument is rather simple: if $|\mathcal{A}(x)| > 0$ for all x in ϕ , we start with x_1 and build an infinite chain $\{x_i, i = 1, 2, \dots\}$ such that $x_1 \leftarrow x_2 \leftarrow x_3 \dots$. By the transitivity of \leftarrow , we have $\{x_i, i = 1, 2, \dots\} \subseteq \mathcal{A}(x_1)$. Thus $|\mathcal{A}(x_1)| = \infty$, which is a contradiction).

Now suppose that $e_\infty(x)$ is uniquely determined for every $x \in \phi$ such that $|\mathcal{A}(x)| < k$. Consider $x \in \phi$ such that $|\mathcal{A}(x)| = k$ (if such x exists), then

$$e_\infty(x) = \prod_{y \in \phi, (y,x) \in \mathcal{E}} (1 - e_\infty(y)), \quad (4.4)$$

by definition. As $y \in \mathcal{A}(x)$ for all $y \in \phi$ such that $(y,x) \in \mathcal{E}$ and $|\mathcal{A}(x)| = k$ we have that the left-hand side is a product of finitely many terms. Moreover, by transitivity of \leftarrow , we know that $\mathcal{A}(y) \subset \mathcal{A}(x)$ for all $y \in \mathcal{A}(x)$. Hence, $|\mathcal{A}(y)| < |\mathcal{A}(x)| = k$ for all $y \in \mathcal{A}(x)$. Then, by the induction hypothesis, every $e_\infty(y)$ term appearing in the left-hand side is uniquely determined, so $e_\infty(x)$ is uniquely determined. \square

The subset ϕ_∞ produced by the ∞ -Matérn model is defined as

$$\phi_\infty = \{x_i \in \phi \text{ s.t. } e_\infty(x) = 1\}. \quad (4.5)$$

It is easily checked that

$$\phi_\infty = \{x_i \in \phi \text{ s.t. for all } y \in \phi_\infty, c(x, y) = 0 \Rightarrow t(x) < t(y)\},$$

and that when ϕ contains finitely many points, ϕ_∞ and ϕ_{III} are identical. This justifies our claim that the ∞ -Matérn model is the extension of Matérn type III model to the case where ϕ may be countably infinite and its associated conflict graph has the finite history property.

4.2 ∞ -Matérn Construction as the Limit of k -Matérn Constructions

Let a sequence of functions $\{e_k, k = 1, 2, \dots\}$ which take elements of ϕ as argument be defined recursively by

$$e_1(x) = \begin{cases} 1 & \text{if } \mathcal{A}(x) = \emptyset, \\ 0 & \text{otherwise;} \end{cases} \quad (4.6)$$

$$e_{k+1}(x) = \prod_{y \in \phi, (y,x) \in \mathcal{E}} (1 - e_k(y)), \quad (4.7)$$

where the product taken over the empty set is 1 by convention.

We first characterize the k -Matérn model in terms of the e_k function.

Proposition 2 *For every $k \in \mathbb{Z}^+$*

$$\phi_k = \{x \in \phi \text{ s.t. } e_k(x) = 1\}.$$

Proof. We use induction on k . The base case $k = 1$ is easily verified. Suppose that the result holds for some $k \geq 1$: $x \in \phi_k \Leftrightarrow e_k(x) = 1$ for all x in ϕ . For $k + 1$, we have

$$\begin{aligned} \forall x \in \phi : x \in \phi_{k+1} &\Leftrightarrow (\forall y \in \phi_k : c(x, y) = 1 \Rightarrow t(x) < t(y)) \\ &\Leftrightarrow (\forall y \in \phi_k : (y, x) \notin \mathcal{E}) \text{ (by definition of } \mathcal{E}) \\ &\Leftrightarrow (\forall y \in \phi : y \in \phi_k \Rightarrow (y, x) \notin \mathcal{E}) \\ &\Leftrightarrow (\forall y \in \phi : (y, x) \in \mathcal{E} \Rightarrow y \notin \phi_k) \\ &\Leftrightarrow (\forall y \in \phi, (y, x) \in \mathcal{E} : y \notin \phi_k) \\ &\Leftrightarrow (\forall y \in \phi, (y, x) \in \mathcal{E} : e_k(y) = 0) \\ &\Leftrightarrow \prod_{y \in \phi, (y,x) \in \mathcal{E}} (1 - e_k(y)) = 1 \\ &\Leftrightarrow e_{k+1}(x) = 1 \text{ (by definition).} \end{aligned}$$

□

In other words, the functions $\{e_k, k = 1, 2, \dots\}$ defined in (4.6) and (4.7) are exactly the indicators that a point in ϕ belongs to the sets $\{\phi_k, k = 1, 2, \dots\}$ respectively. By simple induction arguments, we can also prove that

$$\begin{aligned} e_{2k+1}(x) &\leq e_{2k}(x) \text{ for all } k \in \mathbb{Z}^+, x \in \phi, \\ e_{2k+1}(x) &\leq e_{2k+3}(x) \text{ for all } k \in \mathbb{Z}^+, x \in \phi, \\ e_{2k+2}(x_i) &\leq e_{2k}(x) \text{ for all } k \in \mathbb{Z}^+, x \in \phi. \end{aligned}$$

So, we can deduce that $\phi_1 \subseteq \phi_3 \subseteq \dots$ and $\phi_0 \supseteq \phi_2 \supseteq \dots$, and hence

$$\bigcup_{k=0}^{\infty} \phi_{2k+1} \subseteq \bigcap_{k=0}^{\infty} \phi_{2k}. \quad (4.8)$$

Note that all the above observations hold even when the conflict graph does not have the finite history property. We now show that when the conflict graph does have the finite history property, $\bigcup_{k=0}^{\infty} \phi_{2k+1} = \bigcap_{k=0}^{\infty} \phi_{2k} = \phi_{\infty}$ and this justifies the ∞ subscript in ϕ_{∞} . To this end, the result of the next proposition is sufficient.

Proposition 3 *When the conflict graph \mathcal{G} has the finite history property, for any point x_i in ϕ ,*

$$e_{\infty}(x) = \lim_{k \rightarrow \infty} e_k(x).$$

Proof. We prove by induction on $|\mathcal{A}(x)|$ that

$$e_{|\mathcal{A}(x)|+1}(x) = e_{|\mathcal{A}(x)|+2}(x) = \dots = e_{\infty}(x).$$

The base case is when $|\mathcal{A}(x)| = 0$. In this case $e_1(x) = e_2(x) = \dots = e_{\infty}(x) = 1$ by definition. Moreover

$$e_k(x) = \prod_{x_j \in \phi, (y, x) \in \mathcal{E}} (1 - e_{k-1}(y)) = 1,$$

since $\{x_j \in \phi \text{ s.t. } (x_j, x_i) \in \mathcal{E}\} \subset \mathcal{A}(x_i) = \emptyset$ and the product over an empty set is 1 by convention.

Now suppose that the result holds for all y such that $|\mathcal{A}(y)| \leq k$, for some $k \geq 0$. Consider an x such that $|\mathcal{A}(x)| = k + 1$ (if such x exists). We have for all l ,

$$e_l(x) = \prod_{y \in \phi, (y, x) \in \mathcal{E}} (1 - e_{l-1}(y)).$$

Note that for all y such that $(y, x) \in \mathcal{E}$, we must have $|\mathcal{A}(y)| \leq k$. By the induction hypothesis, $e_{l-1}(y) = e_{\infty}(y)$ for such y and for $l > k + 2$. Hence, for all $l > k + 2$,

$$e_l(x) = \prod_{y \in \phi, (y, x) \in \mathcal{E}} (1 - e_{l-1}(y)) = \prod_{y \in \phi, (y, x) \in \mathcal{E}} (1 - e_{\infty}(y)) = e_{\infty}(x).$$

□

5 Poisson Rain with Random Conflict Relation and its Matérn Models

5.1 Poisson Rain with Random Conflict Relation

Definition 1 *A Poisson Rain with ground intensity Λ is a PPP $\{(x, t(x))\}$ in $\mathbb{R}^2 \times \mathbb{R}^+$ of intensity measure $\Lambda \times \mathcal{L}$ with \mathcal{L} the Lebesgue measure.*

Each 'point' in Φ is a pair $(x, t(x))$ with $x \in \mathbb{R}^2$ and $t(x) \in \mathbb{R}^+$. The x component is understood as the position of a point and $t(x)$ is understood as the timer of the point. The name Poisson Rain stems from the interpretation of Φ as a collection of raindrops falling from the sky, the timer of a point is the time when it hits the ground and its position is the place where it does so. By abuse of notation, for each $x \in \mathbb{R}^2$, we write $x \in \Phi$ for "there exists a t such that $(x, t) \in \Phi$ ". So, when we refer to a point of Φ as a pair of location-timer, we use the pair notation (x, t) , and when we refer to it as a point in \mathbb{R}^2 , we use the single element x notation.

Remark 1 *The Poisson Rain considered here is a special case of the extended Marked Point Process introduced in [5, Definition 9.1.VI, p. 7]. Note that the extended MPP in [5] is used to construct the counting measure of a purely atomic random measure, where the mark of a point is used to represent the mass of the random measure at that point. As the mark of a point is used here to represent its arrival time, we use here the name Poisson Rain instead of extended marked Poisson Point Process.*

Let h be a function satisfying (5.1). The random conflict relation is extended to the Poisson Rain as follows:

Definition 2 *A Poisson Rain with Random Conflict Relation (PRRCR) with ground intensity Λ and expected conflict function h is a pair (Φ, C) where Φ is a Poisson Rain with ground intensity Λ and $C = \{C(x, y), x, y \in \Phi\}$ is a family of $\{0, 1\}$ value r.v.s indexed by unordered pairs of locations in Φ satisfying*

- 1 C is non-reflexive and symmetrical a.s.;
- 2 given a realization of Φ , C is a family of independent r.v.s with the exceptions given by condition 1; and
- 3 $\mathbb{P}(C(x, y) \mid \Phi \text{ and } x, y \in \Phi) = h(x, y)$.

For completeness, we provide here a construction of a PRRCR. Let $\{\Psi_i, i = 1, 2, \dots\}$ be a family of i.i.d. MPPPs with i.i.d. marks of ground intensity Λ . Each point x in Ψ_i is equipped with a mark $\mathbf{u}(x) = \{\tau(x), u_{j,k}(x), j, k = 1, 2, \dots\}$ which is a family of i.i.d. r.v.s uniformly distributed in $[0, 1]$. Let

$$\Psi'_i := \{(x, \tau(x) + i, \{u_{j,k}(x)\}) \text{ for all } (x, \tau(x), \{u_{j,k}(x)\}) \in \Psi_i\}.$$

The Poisson Rain Φ is defined as $\bigcup_{i=1}^{\infty} \Psi'_i$. To determine the random conflict relation, for each x in Φ , we number the points in Ψ'_i in the increasing order of their distance to the centre of the space and associate to the j^{th} point in this numbering the r.v. $u_{i,j}(x)$ in the mark of x . Now, consider any two points x, y in Φ . Let $u_{i,j}(x)$ be the r.v. corresponding to y in the mark of x and $u_{k,l}(y)$ be the r.v. corresponding to x in the mark of y , we let $C(x, y) = 1$ iff $\min(u_{k,l}(y), u_{i,j}(x)) > 1 - \sqrt{h(x, y)}$. It is then easily verified that (Φ, C) defined in this manner is indeed a PRRCR with ground intensity Λ and expected conflict function h .

5.2 ∞ -Matérn Construction of Poisson Rain with Random Conflict Relations

Throughout this paper, we assume that the measure Λ and the function h satisfy

$$\sup_{x \in \mathbb{R}^d} \int_{\mathbb{R}^d} h(x, y) dy = \mathcal{N} < \infty. \quad (5.1)$$

The main result of this section is

Proposition 4 *For any PRRCR Φ of ground intensity measure Λ and expected conflict function h satisfying (5.1), its corresponding conflict graph has the finite history property (see definition in Subsection 4.1) a.s.*

Proof. Consider a typical point x in Φ . Recall that $\mathcal{G} = (\Phi, \mathcal{E})$ is the conflict graph and $\mathcal{A}(x)$ is the set of ancestors of x in the conflict graph. It is sufficient to prove that $\mathcal{A}(x)$ is finite for every x . Let

$$\begin{aligned} \mathcal{A}^{(l)}(x) = \{ & y \in \Phi \text{ s.t. exists } x_0, x_1, \dots, x_l \in \Phi \\ & \text{s.t. } x_0 = x, x_l = y \text{ and } (x_1, x_0), \dots, (x_l, x_{l-1}) \in \mathcal{E} \}. \end{aligned}$$

$\mathcal{A}(x)$ can be rewritten as:

$$\mathcal{A}(x) = \bigcup_{l=1}^{\infty} \mathcal{A}^{(l)}(x).$$

We now prove that $\mathbf{E} [|\mathcal{A}^{(l)}(x)|] \leq \frac{t(x)^l \mathcal{N}^l}{l!}$. First notice that

$$\begin{aligned} |\mathcal{A}^{(l)}(x)| &\leq \sum_{x_1, \dots, x_l \in \Phi} \mathbf{1}_{(x_1, x) \in \mathcal{E}} \prod_{k=2}^l \mathbf{1}_{(x_k, x_{k-1}) \in \mathcal{E}} \\ &= \sum_{x_1, \dots, x_l \in \Phi, x_0 = x} \prod_{k=0}^{l-1} C(x_k, x_{k+1}) \mathbf{1}_{t(x_k) > t(x_{k+1})}. \end{aligned}$$

We consider Φ as a PPP of intensity $\Lambda \times \mathcal{L}$ in $\mathbb{R}^d \times \mathbb{R}^+$, with \mathcal{L} Lebesgue measure, and apply the multivariate Campbell formula to get

$$\begin{aligned}
\mathbb{E} \left[|\mathcal{A}^{(l)}(x)| \right] &\leq \mathbb{E} \left[\sum_{x_0, \dots, x_l \in \Phi, x_0 = x} \prod_{k=0}^{l-1} C(x_k, x_{k+1}) \mathbf{1}_{t(x_k) > T(x_{k+1})} \right] \\
&= \int_{(\mathbb{R}^d)^l} \int_{(\mathbb{R}^+)^l} \mathbf{1}_{t(x) > t_1 > t_2 > \dots > t_l} h(x, x_1) \prod_{k=1}^{l-1} h(x_k, x_{k+1}) \\
&\quad dt_1 \dots dt_l \Lambda(dx_1) \dots \Lambda(dx_l) \\
&= \int_{(\mathbb{R}^d)^l} \frac{t(x)^l}{l!} h(x, x_1) \prod_{k=1}^{l-1} h(x_k, x_{k+1}) \Lambda(dx_1) \dots \Lambda(dx_l).
\end{aligned}$$

As h and Λ satisfy the condition (5.1), we deduce that

$$\begin{aligned}
\mathbb{E} \left[|\mathcal{A}^{(l)}(x)| \right] &\leq \int_{(\mathbb{R}^d)^l} \frac{t(x)^l}{l!} h(x, x_1) \prod_{k=1}^{l-1} h(x_k, x_{k+1}) \Lambda(dx_1) \dots \Lambda(dx_l) \\
&\leq \frac{t(x)^l}{l!} \mathcal{N}^l.
\end{aligned}$$

So

$$\mathbb{E} [|\mathcal{A}(x)|] \leq \sum_{l=1}^{\infty} \mathbb{E} [|\mathcal{A}^{(l)}(x)|] \leq \sum_{l=1}^{\infty} \frac{t(x)^l}{l!} \mathcal{N}^l = \exp\{t(x)\mathcal{N}\} < \infty.$$

This implies that $|\mathcal{A}(x)| < \infty$ a.s. \square

In particular, Proposition 4 shows that when a PRRCR satisfies (5.1), its ∞ -Matérn model is well defined and is the *limit* of the k -Matérn models.

5.3 Timer-based Restrictions and k -Matérn Models

As we will see in the next sections, to study the distribution of the PPs induced by the Matérn models of the PRRCRs, it is useful to divide these PPs to thin layers such that each layer looks like a Poisson PP. Such a partition is defined in this subsection. Given a PRRCR Φ , we define the restriction $T_{s,t}$ to the interval $[s, t)$ as

$$T_{s,t}(\Phi) = \{x \in \Phi \text{ s.t. } t(x) \in [s, t)\}. \quad (5.2)$$

This restricted version of Φ inherits the natural conflict relation from Φ . When $s = 0$, the above notation is reduced to $T_t(\Phi)$. Consider $T_t(\Phi)$ as a PRRCR, we can easily verify that the k -Matérn construction is applicable to $T_{s,t}(\Phi)$ and the ∞ -Matérn type construction is also applicable a.s. given that Λ and h satisfy (5.1). In particular, let the constructed PPs inherit the natural conflict relation from their original PRRCR. The following facts can be easily proved:

- $T_t(\mathcal{M}_j(\Phi)) = \mathcal{M}_j(T_t(\Phi))$ for $j = 0, 1, \dots, \infty$;
- $\mathcal{M}_j(\Phi) = \{x \text{ s.t. } C(x, y) = 0 \forall y \in T_{t(x)}(\mathcal{M}_{j-1}(\Phi))\}$ for $j = 0, 1, \dots$; and
- $\mathcal{M}_\infty(\Phi) = \{x \text{ s.t. } C(x, y) = 0 \forall y \in T_{t(x)}(\mathcal{M}_\infty(\Phi))\}$.

In other words, the first claim asserts that the restriction to $[0, t]$ of the Matérn models of Φ are the same as the Matérn models of the restriction to $[0, t]$ of Φ while the two other claims are just reformulations of the Matérn models definitions. These three claims are based on the fact that for $j = 1, 2, \dots, \infty$, the event $x \in \mathcal{M}_j(\Phi)$ depends only on the realization of the points in Φ whose timers are smaller than $t(x)$.

We conclude with a result that will be used frequently in the next section. It allows us to approximate the PPs $T_{s,t}(\mathcal{M}_j(\Phi))$, $j = 1, 2, \dots, \infty$ by other PPs which have much simpler structures.

Proposition 5 *For every realization of the PRRCR (Φ, C) such that its associated conflict graph has the finite history property and for every $0 < s < t$,*

$$\begin{aligned} \Delta_{j,d,s,t} &\subseteq T_{s,t}(\mathcal{M}_j(\Phi)) \subseteq \Delta_{j,u,s,t} \text{ for } j = 1, 2, \dots; \\ \Delta_{\infty,d,s,t} &\subseteq T_{s,t}(\mathcal{M}_\infty(\Phi)) \subseteq \Delta_{\infty,u,s,t}, \end{aligned} \quad (5.3)$$

where

$$\begin{aligned} \Delta_{j,d,s,t} &= \{x \in T_{s,t}(\Phi) \text{ s.t. } C(x, y) = 0 \forall y \in T_s(\mathcal{M}_{j-1}(\Phi)) \cup T_{s,t}(\Phi)\}; \\ \Delta_{j,u,s,t} &= \{x \in T_{s,t}(\Phi) \text{ s.t. } C(x, y) = 0 \forall y \in T_s(\mathcal{M}_{j-1}(\Phi))\}; \\ \Delta_{\infty,d,s,t} &= \{x \in T_{s,t}(\Phi) \text{ s.t. } C(x, y) = 0 \forall y \in T_s(\mathcal{M}_\infty(\Phi)) \cup T_{s,t}(\Phi)\}; \\ \Delta_{\infty,u,s,t} &= \{x \in T_{s,t}(\Phi) \text{ s.t. } C(x, y) = 0 \forall y \in T_s(\mathcal{M}_\infty(\Phi))\}. \end{aligned} \quad (5.4)$$

Proof. Since $\mathcal{M}_j(\Phi) = \{x \text{ s.t. } C(x, y) = 0 \forall y \in T_{t(x)}(\mathcal{M}_{j-1}(\Phi))\}$ and $T_s(\Phi) \subseteq T_{t(x)}(\Phi) \subseteq T_t(\Phi)$ for every $x \in T_{s,t}(\Phi)$, the first double inclusion follows directly. The second one is proved similarly using the third claim above and taking into account that $T_s(\mathcal{M}_\infty(\Phi)) \subseteq T_{t(x)}(\mathcal{M}_\infty(\Phi)) \subseteq T_s(\mathcal{M}_\infty(\Phi)) \cup T_{s,t}(\Phi)$ for every $x \in T_{s,t}(\Phi)$. \square

6 Probability Generating Functionals

This section gathers the main results of this paper regarding the evolution of the p.g.fl.s of the k -Matérn models and the ∞ -Matérn model. Even though it is harder to define, the p.g.fl.s of the ∞ -Matérn model is easier to work with. For this reason, we give the results concerning these p.g.fl.s in Subsection 6.2 after some background on p.g.fl.s of PPs in Subsection 6.1. Then, the method is extended to study the p.g.fl.s of the k -Matérn models in Subsection 6.3.

6.1 Preliminaries

For any PP Ξ , we define for each function v taking value in $[0, 1]$

$$G_{\Xi}(v) = \mathbb{E} \left[\prod_{x \in \Xi} v(x) \right]. \quad (6.1)$$

This is called the probability generating functional (p.g.fl) of Ξ at v . For the p.g.fl to be well-defined and non-trivial, we need that $|\sum_{x \in \Xi} \log(v(x))| < \infty$ a.s. As $|\log(v(x))| \leq (1 - v(x))$, we consider only the p.g.fl of Ξ at functions v satisfying

$$\mathbb{E} \left[\sum_{x \in \Xi} (1 - v(x)) \right] = \int_{\mathbb{R}^d} (1 - v(x)) m_{\Xi}(dx) < \infty, \quad (6.2)$$

with $m_{\Xi}(\cdot)$ the intensity (first moment) measure of Ξ . An important special case is the p.g.fl of PPPs, which can be computed in closed forms [5],[1].

Theorem 1 *Let Ψ be a PPP of intensity measure Λ and v is a function taking value in $[0, 1]$ such that $\int_{\mathbb{R}^d} (1 - v(x)) \Lambda(dx) < \infty$. Then,*

$$G_{\Psi}(v) = \exp \left\{ - \int_{\mathbb{R}^d} (1 - v(x)) \Lambda(dx) \right\}. \quad (6.3)$$

6.2 ∞ -Matérn Models

We are interested in the functionals $f_{k,\Lambda}(t, v) := G_{T_{0,t}(\mathcal{M}_k(\Phi))}(v(\cdot))$ with $t \geq 0$, where Φ is a PRRCR with ground intensity Λ , expected conflict function h and v is a function from \mathbb{R}^2 to $[0, 1]$ such that:

$$\int_{\mathbb{R}^2} (1 - v(x)) \Lambda(dx) < \infty. \quad (6.4)$$

In the other words, for each fixed t this gives us the p.g.fl of the PPs induced by Matérn models restricted to $[0, t]$.

Remarks

- The condition (6.4) is equivalent to $\mathbb{E} \left[\sum_{x \in T_{0,t}(\Phi)} (1 - v(x)) \right] < \infty$ (Campbell's formula) for every $t \geq 0$. Thus, this condition guarantees that the p.g.fl of Φ is well-defined and non-trivial at v . In particular, since

$$T_{0,t}(\mathcal{M}_k(\Phi)) \subset T_{0,t}(\Phi) \text{ a.s. ,}$$

we have $\mathbb{E} \left[\sum_{x \in T_{0,t}(\mathcal{M}_k(\Phi))} (1 - v(x)) \right] < \infty$, so that $G_{T_{0,t}(\mathcal{M}_k(\Phi))}$ is well-defined at v .

- Although there are functions v such that $G_{T_{0,t}(\mathcal{M}_k(\Phi))}$ is well-defined at v while (6.4) is not satisfied, we do not consider this case here for two reasons:
 - All information about the distribution of a PP can be extracted from its p.g.fl at functions v having bounded support. These functions satisfy (6.4) automatically.
 - As we see in Subsections 6.2 and 6.3, this condition guarantees nice convergence properties.

If not otherwise stated, we assume that every function considered here satisfies (6.4). Fix such a function v , we first show that $f_{\infty,\Lambda}(t, v)$ is continuous in t .

Proposition 6 *For every function v satisfying condition (6.4), $f_{\infty,\Lambda}(t, v)$ is continuous in t .*

Proof. For every t and ϵ positive

$$\begin{aligned} f_{\infty,\Lambda}(t + \epsilon, v) &= \mathbb{E} \left[\prod_{x \in T_{t+\epsilon}(\mathcal{M}_{\infty}(\Phi))} v(x) \right] \\ &= \mathbb{E} \left[\prod_{x \in T_t(\mathcal{M}_{\infty}(\Phi))} v(x) \prod_{x \in T_{t,t+\epsilon}(\mathcal{M}_{\infty}(\Phi))} v(x) \right]. \end{aligned}$$

As $T_{t,t+\epsilon}(\mathcal{M}_{\infty}(\Phi)) \subseteq T_{t,t+\epsilon}(\Phi)$ a.s., we deduce that

$$1 \geq \prod_{x \in T_{t,t+\epsilon}(\mathcal{M}_{\infty}(\Phi))} v(x) \geq \prod_{x \in T_{t,t+\epsilon}(\Phi)} v(x) \text{ a.s.}$$

As $T_{t,t+\epsilon}$ is independent with $T_t(\mathcal{M}_{\infty}(\Phi))$,

$$\begin{aligned} f_{\infty,\Lambda}(t, v) e^{-\epsilon \int_{\mathbb{R}^2} (1-v(x)) \Lambda(dx)} &= \mathbb{E} \left[\prod_{x \in T_t(\mathcal{M}_{\infty}(\Phi))} v(x) \prod_{x \in T_{t,t+\epsilon}(\Phi)} v(x) \right] \\ &\leq \mathbb{E} \left[\prod_{x \in T_{t+\epsilon}(\mathcal{M}_{\infty}(\Phi))} v(x) \right] \\ &= f_{\infty,\Lambda}(t + \epsilon, v) \leq f_{\infty,\Lambda}(t, v), \end{aligned}$$

where the inequality comes from the fact that $v \leq 1$. Following the same method, we get

$$f_{\infty,\Lambda}(t - \epsilon, v) e^{-\epsilon \int_{\mathbb{R}^2} |1-v(x)| \Lambda(dx)} \leq f_{\infty,\Lambda}(t, v) \leq f_{\infty,\Lambda}(t - \epsilon, v).$$

Letting ϵ go to 0 completes this proof. \square

Let H be the mapping that associates to a function $v : \mathbb{R}^2 \rightarrow [0, 1]$ and a point $x \in \mathbb{R}^2$ the function

$$H(v, x) : y \mapsto v(y)(1 - h(x, y)) \quad (6.5)$$

from \mathbb{R}^2 to $[0, 1]$.

Theorem 2 *For any locally finite measure Λ , the functional $f_{\infty, \Lambda}$ satisfies the following system of equations,*

$$\begin{aligned} f_{\infty, \Lambda}(0, v) &= 1; \\ \frac{df_{\infty, \Lambda}(t, v)}{dt} &= - \int_{\mathbb{R}^2} f_{\infty, \Lambda}(t, H(v, x))(1 - v(x)) \Lambda(dx). \end{aligned} \quad (6.6)$$

The main idea behind this theorem is to divide $\mathcal{M}_{\infty}(\Phi)$ into very thin layers $T_{t, t+\epsilon}(\mathcal{M}_{\infty}(\Phi))$. For $\epsilon > 0$ small enough, the points in each layer are so sparse that there is almost no conflict between them. Then we can consider each layer as a PPP.

In particular, we need to prove that

$$\lim_{\epsilon \rightarrow \infty} \frac{f_{\infty, \Lambda}(t + \epsilon, v) - f_{\infty, \Lambda}(t, v)}{\epsilon} = - \int_{\mathbb{R}^2} f_{\infty, \Lambda}(t, H(v, x))(1 - v(x)) \Lambda(dx); \quad (6.7)$$

$$\lim_{\epsilon \rightarrow \infty} \frac{f_{\infty, \Lambda}(t, v) - f_{\infty, \Lambda}(t - \epsilon, v)}{\epsilon} = - \int_{\mathbb{R}^2} f_{\infty, \Lambda}(t, H(v, x))(1 - v(x)) \Lambda(dx). \quad (6.8)$$

For this purpose, we need the following lemmas.

Lemma 1 *Let Ξ be a PP and v is a function taking value in $[0, 1]$ such that*

$$\mathbb{E} \left[\sum_{x \in \Xi} (1 - v(x)) \right] < \infty.$$

We have

$$\prod_{x \in \Xi} v(x) = 1 + \sum_{i=1}^{\infty} (-1)^i \sum_{(x_1, \dots, x_i) \in \Xi^{i!}} \prod_{j=1}^i (1 - v(x_j)) \text{ a.s.}, \quad (6.9)$$

where $\Xi^{(i!)}$ is the set of unordered i -tuples of mutually different points in Ξ .

Proof. Since $\sum_{x \in \Xi} \log(v(x)) \leq \sum_{x \in \Xi} (1 - v(x)) < \infty$ a.s.,

$$\prod_{x \in \Xi} v(x) = \exp \left\{ \sum_{x \in \Xi} \log(v(x)) \right\}$$

is well-defined and is finite a.s.

Now we need to prove that the series in the right hand side of (6.9) converges. For this purpose, it is sufficient to show that

$$1 + \sum_{i=1}^{\infty} \sum_{(x_1, \dots, x_i) \in \Xi^{i!}} \prod_{j=1}^i (1 - v(x_j)) < \infty \text{ a.s.}$$

Note that

$$\begin{aligned} \sum_{(x_1, \dots, x_i) \in \Xi^{i!}} \prod_{j=1}^i (1 - v(x_j)) &= \frac{1}{i!} \sum_{x_1, \dots, x_i \text{ mutually different} \in \Xi} \prod_{j=1}^i (1 - v(x_j)) \\ &\leq \frac{1}{i!} \left(\sum_{x \in \Xi} (1 - v(x)) \right)^i. \end{aligned}$$

Hence,

$$\begin{aligned} 1 + \sum_{i=1}^{\infty} \sum_{(x_1, \dots, x_i) \in \Xi^{i!}} \prod_{j=1}^i (1 - v(x_j)) &\leq 1 + \sum_{i=1}^{\infty} \frac{1}{i!} \left(\sum_{x \in \Xi} (1 - v(x)) \right)^i \\ &= \exp \left\{ \left(\sum_{x \in \Xi} (1 - v(x)) \right) \right\} < \infty. \end{aligned}$$

The equality can now be obtained by writing

$$\prod_{x \in \Xi} v(x) = \prod_{x \in \Xi} \left(1 - (1 - v(x)) \right).$$

□

Lemma 2 *Let (Φ, C) be a PRRCR with ground intensity Λ and expected conflict function h . For every $t \geq 0$ and $\epsilon > 0$ small enough,*

$$\begin{aligned} &\left| \mathbb{E} \left[\prod_{x \in T_{t, t+\epsilon}(\mathcal{M}_{\infty}(\Phi))} v(x) \middle| \Phi_t \right] - 1 + \epsilon \int_{\mathbb{R}^2} (1 - v(x)) \Lambda_{\infty, t}(dx) \right| \\ &\leq \epsilon^2 \left(2 \left(\int_{\mathbb{R}^2} (1 - v(x)) \Lambda(dx) \right)^2 + \overline{H} \int_{\mathbb{R}^2} (1 - v(x)) \Lambda(dx) \right) \text{ a.s. }, \end{aligned} \quad (6.10)$$

where \overline{H} is defined in (5.1) and $\Lambda_{\infty, t}$ is the random measure in \mathbb{R}^2 satisfying

$$\Lambda_{\infty, t}(dx) = \prod_{y \in T_t(\mathcal{M}_{\infty}(\Phi))} (1 - h(x, y)) \Lambda(dx). \quad (6.11)$$

Proof. See Appendix B.

Note that given Φ_t , the p.g.fl of $\Delta_{\infty, u, t, t+\epsilon}$, which is a PPP of intensity measure $\epsilon \Lambda_{\infty, t}$, is

$$G_{\Delta_{\infty, u, t, t+\epsilon}}(v) = \exp \left\{ -\epsilon \int_{\mathbb{R}^2} (1 - v(x)) \Lambda_{\infty, t}(dx) \right\}.$$

Hence,

$$\begin{aligned} \lim_{\epsilon \rightarrow 0} \frac{G_{\Delta_{\infty, u, t, t+\epsilon}}(v) - 1}{\epsilon} &= - \int_{\mathbb{R}^2} (1 - v(x)) \Lambda_{\infty, t}(dx) \\ &= \lim_{\epsilon \rightarrow 0} \frac{G_{T_{t, t+\epsilon}(\mathcal{M}_{\infty}(\Phi))}(v) - 1}{\epsilon}. \end{aligned}$$

Thus, Lemma 2 justifies our intuition that when the time scale is small, the effect of conflict is negligible, and we can regard the thin layer $T_{t, t+\epsilon}(\mathcal{M}_{\infty}(\Phi))$ as a PPP. Such property, which we call the *quasi-Poisson* property, plays an important role in the subsequent studies.

Now we can proceed to the proof of Theorem 2, where ∞ and Λ subscripts are dropped to avoid cumbersome notation. Note that for $r > s$

$$f(r, v) - f(s, v) = \mathbb{E} \left[\prod_{x \in T_s(\mathcal{M}_{\infty}(\Phi))} v(x) \left(\prod_{y \in T_{s, r}(\mathcal{M}_{\infty}(\Phi))} v(y) - 1 \right) \right].$$

In order to evaluate the last expression, we need the conditional probability

$$\mathbb{E} \left[\prod_{y \in T_{s, r}(\mathcal{M}_{\infty}(\Phi))} v(y) - 1 \middle| \Phi_s \right]. \quad (6.12)$$

Put $s = t$ and $r = t + \epsilon$, by Lemma 2,

$$\begin{aligned} & \left| \left(\mathbb{E} \left[\prod_{y \in T_{t, t+\epsilon}(\mathcal{M}_{\infty}(\Phi))} v(y) \middle| \Phi_t \right] - 1 \right) \epsilon^{-1} + \int_{\mathbb{R}^2} (1 - v(x)) \Lambda_{\infty, t}(dx) \right| \\ & \leq \epsilon \left(2 \left(\int_{\mathbb{R}^2} (1 - v(x)) \Lambda(dx) \right)^2 + \overline{H} \int_{\mathbb{R}^2} (1 - v(x)) \Lambda(dx) \right) \text{ a.s.} \end{aligned}$$

Let $\mathfrak{C} = 2 \left(\int_{\mathbb{R}^2} (1 - v(x)) \Lambda(dx) \right)^2 + \overline{H} \int_{\mathbb{R}^2} (1 - v(x)) \Lambda(dx)$, we have

$$\begin{aligned} & \left| \frac{f(t + \epsilon, v) - f(t, v)}{\epsilon} + \mathbb{E} \left[\prod_{y \in T_t(\mathcal{M}_{\infty}(\Phi))} v(y) \left(\int_{\mathbb{R}^2} (1 - v(x)) \Lambda_{\infty, t}(dx) \right) \right] \right| \\ & \leq \epsilon \mathfrak{C} \mathbb{E} \left[\prod_{y \in T_t(\mathcal{M}_{\infty}(\Phi))} v(y) \right] = \epsilon \mathfrak{C} f(t, v) \leq \epsilon \mathfrak{C}. \end{aligned} \quad (6.13)$$

Moreover,

$$\begin{aligned}
& \mathbb{E} \left[\prod_{y \in T_t(\mathcal{M}_\infty(\Phi))} v(y) \left(\int_{\mathbb{R}^2} (1 - v(x)) \Lambda_{\infty, t}(dx) \right) \right] \\
&= \mathbb{E} \left[\prod_{y \in T_t(\mathcal{M}_\infty(\Phi))} v(y) \left(\int_{\mathbb{R}^2} (1 - v(x)) \left(\prod_{y \in T_t(\mathcal{M}_\infty(\Phi))} (1 - h(x, y)) \right) \Lambda(dx) \right) \right] \\
&= \mathbb{E} \left[\int_{\mathbb{R}^2} (1 - v(x)) \left(\prod_{y \in T_t(\mathcal{M}_\infty(\Phi))} v(y) (1 - h(x, y)) \right) \Lambda(dx) \right] \\
&= \mathbb{E} \left[\int_{\mathbb{R}^2} (1 - v(x)) \left(\prod_{y \in T_t(\mathcal{M}_\infty(\Phi))} H(v, x)(y) \right) \Lambda(dx) \right].
\end{aligned}$$

As the term inside of the integration is a positive r.v. we can change the order of expectation and integration,

$$\begin{aligned}
& \mathbb{E} \left[\int_{\mathbb{R}^2} (1 - v(x)) \prod_{y \in T_t(\mathcal{M}_\infty(\Phi))} H(v, x)(y) \Lambda(dx) \right] \\
&= \int_{\mathbb{R}^2} (1 - v(x)) f(t, H(v, x)) \Lambda(dx).
\end{aligned}$$

Letting ϵ goes to 0 in (6.13) gives us (6.7). To prove (6.8), we put $s = t - \epsilon$ and $r = t$ in (6.12). Proceeding as above, we obtain

$$\begin{aligned}
& \left| \frac{f(t, v) - f(t - \epsilon, v)}{\epsilon} + \mathbb{E} \left[\prod_{y \in T_{t-\epsilon}(\mathcal{M}_\infty(\Phi))} v(y) \left(\int_{\mathbb{R}^2} (1 - v(x)) \Lambda_{\infty, t-\epsilon}(dx) \right) \right] \right| \\
&\leq \epsilon \mathfrak{C} f(t - \epsilon, v) \leq \epsilon \mathfrak{C}.
\end{aligned}$$

We can also show that

$$\begin{aligned}
& \mathbb{E} \left[\prod_{y \in T_{t-\epsilon}(\mathcal{M}_\infty(\Phi))} v(y) \left(\int_{\mathbb{R}^2} (1 - v(x)) \Lambda_{\infty, t-\epsilon}(dx) \right) \right] \\
&= \int_{\mathbb{R}^2} (1 - v(x)) f(t - \epsilon, H(v, x)) \Lambda(dx).
\end{aligned}$$

We then get (6.8) by letting ϵ goes to 0 and using the continuity of f in t (Proposition 6). \square

We can also obtain an upper bound and a lower bound on $f_{\infty, \Lambda}$:

Corollary 1 For every $t > 0$ and every function v satisfying (6.4),

$$\begin{aligned} & \exp \left\{ -t \int_{\mathbb{R}^2} (1 - v(x)) \Lambda(dx) \right\} \leq f_{\infty, \Lambda}(t, v) \\ & \leq 1 - \int_{\mathbb{R}^2} \frac{1 - \exp \left\{ -t \int_{\mathbb{R}^2} (1 - v(y)(1 - h(x, y))) \Lambda(dy) \right\}}{\int_{\mathbb{R}^2} (1 - v(y)(1 - h(x, y))) \Lambda(dy)} (1 - v(x)) \Lambda(dx). \end{aligned} \quad (6.14)$$

Proof. The first inequality comes from the fact that $\mathcal{M}_{\infty}(\Phi_t) \subseteq \Phi_t$ a.s. and from Theorem 1. For the second inequality, we first use Theorem 2 to get

$$f_{\infty, \Lambda}(t, v) = 1 - \int_0^t \int_{\mathbb{R}^2} f_{\infty, \Lambda}(\tau, H(v, x)) (1 - v(x)) \Lambda(dx) d\tau.$$

By the first inequality,

$$f_{\infty, \Lambda}(\tau, H(v, x)) \geq \exp \left\{ -\tau \int_{\mathbb{R}^2} (1 - v(y)(1 - h(x, y))) \Lambda(dy) \right\}.$$

Hence,

$$\begin{aligned} & f_{\infty, \Lambda}(t, v) \\ & \leq 1 - \int_0^t \int_{\mathbb{R}^2} \exp \left\{ -\tau \int_{\mathbb{R}^2} (1 - v(y)(1 - h(x, y))) \Lambda(dy) \right\} (1 - v(x)) \Lambda(dx) d\tau. \end{aligned}$$

We then conclude by using Fubini's theorem. \square

6.3 k -Matérn Models

Unlike the construction of the ∞ -Matérn model, which requires reference to itself, the construction of the k -Matérn model requires reference to the $k - 1$ -Matérn model. Thus, in order to study the p.g.fl.s of the k -Matérn model, we need to consider the joint distribution of all the i -Matérn model for $i = 0, \dots, k$. This can be done by considering the joint p.g.fl.s of these PPs:

$$\begin{aligned} f_{k, \Lambda}(t, v_0, \dots, v_k) &:= G_{T_t(\mathcal{M}_0(\Phi)), \dots, T_t(\mathcal{M}_k(\Phi))}(v_0, \dots, v_k) \\ &:= \mathbf{E} \left[\prod_{i=0}^k \prod_{x \in T_t(\mathcal{M}_i(\Phi))} v_i(x) \right]. \end{aligned}$$

As the PPs $\mathcal{M}_0(\Phi), \dots, T_t(\mathcal{M}_k(\Phi))$ are not mutually disjoint, points in $T_t(\Phi)$ may appear more than once in the above product. Hence, computing this expression can be quite complicated. On the other hand, recall the following relation between $\mathcal{M}_i(\Phi)$,

- $\mathcal{M}_0(\Phi) \supseteq \mathcal{M}_2(\Phi) \cdots$;
- $\mathcal{M}_1(\Phi) \supseteq \mathcal{M}_3(\Phi) \cdots$;
- $\bigcup_{i=0}^{\infty} \mathcal{M}_{2i+1}(\Phi) \subseteq \bigcap_{i=0}^{\infty} \mathcal{M}_{2i}(\Phi)$.

We let

$$\begin{aligned}\mathcal{Q}_{2i}(\Phi) &:= \mathcal{M}_{2i-2}(\Phi) \setminus \mathcal{M}_{2i}(\Phi); \\ \mathcal{Q}_{2i-1}(\Phi) &:= \mathcal{M}_{2i-1}(\Phi) \setminus \mathcal{M}_{2i-3}(\Phi); \\ \mathcal{R}_{2i}(\Phi) &:= \mathcal{M}_{2i}(\Phi) \setminus \mathcal{M}_{2i-1}(\Phi); \\ \mathcal{R}_{2i-1}(\Phi) &:= \mathcal{M}_{2i-2}(\Phi) \setminus \mathcal{M}_{2i-1}(\Phi),\end{aligned}$$

for $i = 1, 2, \dots$ with the convention that $\mathcal{M}_{-1}(\Phi) = \emptyset$. We consider for each k the functional

$$\begin{aligned}g_{k,\Lambda}(t, v_1, \dots, v_{k+1}) &:= G_{T_t(\mathcal{Q}_1(\Phi)), \dots, T_t(\mathcal{Q}_k(\Phi)), T_t(\mathcal{R}_k(\Phi))} \\ &:= \mathbb{E} \left[\prod_{i=1}^k \prod_{x \in T_t(\mathcal{Q}_i(\Phi))} v_i(x) \prod_{x \in T_t(\mathcal{R}_k(\Phi))} v_k(x) \right].\end{aligned}\quad (6.15)$$

The next proposition shows that $f_{k,\Lambda}$ and $g_{k,\Lambda}$ are equivalent. Hence, we can study $g_{k,\Lambda}$ instead of $f_{k,\Lambda}$. As $\mathcal{Q}_1(\Phi), \dots, \mathcal{Q}_k(\Phi), \mathcal{R}_k(\Phi)$ form a partition of Φ , this makes $g_{k,\Lambda}$ easier to work with.

Proposition 7 *The functionals $f_{k,\Lambda}$ depend on the functionals $g_{k,\Lambda}$ in the sense that if we can compute $g_{k,\Lambda}(t, u_1, \dots, u_{k+1})$ for every $t \geq 0$ and for every $k+1$ -tuple of functions (u_1, \dots, u_{k+1}) , then we can compute $f_{k,\Lambda}(t, v_0, \dots, v_k)$ for every $t \geq 0$ and for every $k+1$ -tuple of functions (v_0, \dots, v_k) .*

Proof. Note that, by definition, $\mathcal{Q}_i(\Phi)$ must be either included in $\mathcal{M}_j(\Phi)$ or disjoint with $\mathcal{M}_j(\Phi)$ for every $i, j = 0, 1, \dots$. Similarly, the same thing holds for $\mathcal{R}_i(\Phi)$ and $\mathcal{M}_j(\Phi)$. For each i , let $I_i := \{j \text{ s.t. } \mathcal{Q}_i(\Phi) \subseteq \mathcal{M}_j(\Phi)\}$ and $J_k := \{j \text{ s.t. } \mathcal{R}_k(\Phi) \subseteq \mathcal{M}_j(\Phi)\}$. In particular,

$$\begin{aligned}I_{2i-1} &= \{2i-1, 2i+1, \dots\} \cup \{0, 2, 4, \dots\} \\ I_{2i} &= \{0, 2, \dots, 2i-2\} \\ J_{2i-1} &= \{0, 2, \dots, 2i-2\} \\ J_{2i} &= \{0, 2, \dots, 2i\}.\end{aligned}$$

Then, fix a k , for every i ,

$$\mathcal{M}_i(\Phi) \begin{cases} = \left(\bigcup_{j \text{ s.t. } i \in I_j} \mathcal{Q}_j(\Phi) \right) \cup \mathcal{R}_k(\Phi) & \text{if } i \in J_k, \\ = \bigcup_{j \text{ s.t. } i \in I_j} \mathcal{Q}_j(\Phi) & \text{otherwise.} \end{cases}$$

Hence,

$$\begin{aligned}
& f_{k,\Lambda}(t, v_0, \dots, v_k) \\
&= \mathbf{E} \left[\prod_{i=0}^k \left(\prod_{x \in T_t(\mathcal{M}_i(\Phi))} v_i(x) \right) \right] \\
&= \mathbf{E} \left[\prod_{i=0}^k \left(\prod_{j \text{ s.t. } i \in I_j} \left(\prod_{x \in T_t(\mathcal{Q}_j(\Phi))} v_i(x) \right) \prod_{x \in T_t(\mathcal{R}_k(\Phi))} (v_i(x))^{\mathbf{1}_{i \in J_k}} \right) \right] \\
&= \mathbf{E} \left[\prod_{i=0}^k \left(\prod_{j=1}^k \left(\prod_{x \in T_t(\mathcal{Q}_j(\Phi))} (v_i(x))^{\mathbf{1}_{i \in I_j}} \right) \prod_{x \in T_t(\mathcal{R}_k(\Phi))} (v_i(x))^{\mathbf{1}_{i \in J_k}} \right) \right] \\
&= \mathbf{E} \left[\prod_{j=1}^k \left(\prod_{x \in T_t(\mathcal{Q}_j(\Phi))} v_i(x)^{\sum_{i=0}^k \mathbf{1}_{i \in I_j}} \right) \prod_{x \in T_t(\mathcal{R}_k(\Phi))} v_i(x)^{\sum_{i=0}^k \mathbf{1}_{i \in J_k}} \right]. \quad (6.16)
\end{aligned}$$

Put

$$u_j(x) := \prod_{i=0}^k v_i(x)^{\mathbf{1}_{i \in I_j}},$$

for $j = 1, \dots, k$ and put

$$u_{k+1}(x) := \prod_{i=0}^k v_i(x)^{\mathbf{1}_{i \in J_k}}.$$

The above equalities can be rewritten as

$$f_{k,\Lambda}(t, v_0, \dots, v_k) = g_{k,\Lambda}(t, u_1, \dots, u_{k+1}).$$

□

We now give a system of differential equations that governs the evolution of $g_{k,\Lambda}$ in t .

Theorem 3 *For any locally finite measure Λ , the functional $g_{k,\Lambda}$ is continuous in t and satisfies the following system of equations,*

$$\begin{aligned}
g_{k,\Lambda}(0, \mathbf{v}) &= 1; \\
\frac{dg_{k,\Lambda}(t, \mathbf{v})}{dt} &= - \sum_{i=1}^{k+1} \int_{\mathbb{R}^2} g_{k,\Lambda}(t, \mathbf{H}_{i,k}(\mathbf{v}, x)) (w_i(x) - v_i(x)) \Lambda(dx), \quad (6.17)
\end{aligned}$$

with $\mathbf{v} = \{v_1, \dots, v_{k+1}\}$ is a $k+1$ -tuple of functions from \mathbb{R}^2 to $[0, 1]$ satisfying (6.2), (w_1, \dots, w_{k+1}) is defined as follows

$$\begin{aligned}
w_i &= v_{i+2} \text{ for } i \text{ odd smaller than } k+1; \\
w_i &= v_{i-2} \text{ for } i \text{ even smaller than } k+1; \\
w_{k+1} &= v_k
\end{aligned}$$

when k is even and

$$\begin{aligned} w_i &= v_{i+2} \text{ for } i \text{ odd smaller than } k; \\ w_i &= v_{i-2} \text{ for } i \text{ even smaller than } k+1; \\ w_k &= v_{k+1}; \\ w_{k+1} &= v_{k-1}, \end{aligned}$$

when k is odd where $v_0 = \mathbf{1}$ by convention and

$$\mathbf{H}_{i,k}(\mathbf{v}, x)(y) = (\mathbf{u}_{0,i,k}(y, x), \dots, \mathbf{u}_{k+1,i,k}(y, x)) \quad (6.18)$$

where

$$\begin{aligned} \mathbf{u}_{j,i,k}(y, x) &= v_j(y)(1 - h(x, y)) \text{ if } i-1 \in I_j \text{ and } j \leq k; \\ \mathbf{u}_{k+1,i,k}(y, x) &= v_{k+1}(y)(1 - h(x, y)) \text{ if } i-1 \in J_k; \\ \mathbf{u}_{j,i,k}(y, x) &= v_j(y) \text{ otherwise,} \end{aligned} \quad (6.19)$$

for every $y \in \mathbb{R}^2$.

Proof. See Appendix C. □

7 Reduced Palm Probability Generating Functional

The aim of this section is to derive a similar system of differential equations for the Palm versions of these p.g.fl.s, i.e. the expectation of the product of a function v taken over all points of each of these point processes under its Palm distributions. We limit ourselves to the Matérn models introduced in Section 3. We first derive the first moment measures of the Matérn PPs from their p.g.fl.s following a standard argument in the theory of PPs. Then, by extending this method, the systems of integral equations governing the evolution of the reduced Palm p.g.fl.s of these PPs are also derived.

7.1 Definitions

Let Φ be a PRRCR of intensity measure Λ and expected conflict function h . We define

$$m_{k,\Lambda}(t, B) = \mathbb{E} [T_t(\mathcal{M}_k(\Phi))(B)] \text{ for } k = \overline{0, \infty},$$

for every bounded measurable set B . We can easily prove that for each $t > 0$, $m_{k,\Lambda}(t, \cdot)$, $k = 1, 2, \dots, \infty$ are indeed measures on \mathbb{R}^2 (see [5]). They are called the first moment measures of the Matérn models. As $T_t(\mathcal{M}_k(\Phi))$ are thinning of $T_t(\Phi)$ for $k = \overline{0, \infty}$, their first moment measures must be absolutely continuous

w.r.t. Λ . By abuse of notation, we denote by $m_{k,\Lambda}(t, x)$ the Radon-Nikodym derivative of $m_{k,\Lambda}$ w.r.t. Λ .

Denote by $\mathbf{P}_{x,\Phi}$ the reduced Palm distribution given a point at x of a PP Φ , respectively and denote by $\mathbf{E}_{x,\Phi}$ the corresponding expectation. Note that we consider the reduced Palm distribution here rather than the Palm distribution (see Appendix ?? for definitions). Given the reduced Palm distribution, one can easily compute the Palm distribution by using Proposition 12.

We define

$$f_{y,k,\Lambda}(t, v) = \mathbf{E}_{y, T_t(\mathcal{M}_k(\Phi))} \left[\prod_{x \in T_t(\mathcal{M}_k(\Phi))} v(x) \right] \text{ for } k = \overline{0, \infty}. \quad (7.1)$$

Our objectives are to compute the measures $m_{k,\Lambda}$ and to derive systems of integral equations characterizing the functionals $f_{y,k,\Lambda}$.

7.2 First Moment Measure

These moment measures are computed in terms of the functionals $f_{k,\Lambda}$, $k = \overline{0, \infty}$ as follows.

Proposition 8 *For any locally finite measure Λ and any k from 1 to ∞ , we have,*

$$m_{k,\Lambda}(t, dx) = \int_0^t f_{k-1,\Lambda}(\tau, 1 - h(\cdot, x)) d\tau. \quad (7.2)$$

Proof. Since there is no ambiguity, we drop the subscript Λ for notational convenience.

We start with the case $k = \infty$. Applying Proposition 13 with $v = e^{-s\mathbf{1}_B}$, we get

$$\left. \frac{d}{ds} f_\infty(t, e^{-s\mathbf{1}_B}) \right|_{s=0} = -m_{\infty,\Lambda}(t, B).$$

Moreover, by Theorem 2,

$$f_\infty(t, e^{-s\mathbf{1}_B}) = 1 - \int_0^t \int_{\mathbb{R}^2} f_{\infty,\Lambda}(\tau, H(e^{-s\mathbf{1}_B}, x)) (1 - e^{-s\mathbf{1}_B(x)}) \Lambda(dx) d\tau.$$

Hence,

$$m_\infty(t, B) = \left. \frac{d}{ds} \int_0^t \int_{\mathbb{R}^2} f_{\infty,\Lambda}(\tau, H(e^{-s\mathbf{1}_B}, x)) (1 - e^{-s\mathbf{1}_B(x)}) \Lambda(dx) d\tau \right|_{s=0}.$$

Now we want to change the order of the derivative and the integration in the right hand side. First, the conditions for this must be verified.

Using Proposition 13, we have for all s ,

$$\left| \frac{d}{ds} f_\infty(\tau, H(e^{-s\mathbf{1}_B}, x)) \right| = \left| \int_B f_{y,\infty}(\tau, H(e^{-s\mathbf{1}_B}, x)) m_\infty(\tau, y) \Lambda(dy) \right| \leq \tau \Lambda(B),$$

since $m_{\infty,\Lambda}(\tau, x) < \tau$ for all x (as the ∞ -Matérn model is a thinning of Φ) and $0 \leq H(e^{-s\mathbf{1}_B}, x)(y) \leq 1$ for every x, y in \mathbb{R}^2 . Hence,

$$\begin{aligned} & \left| \frac{d}{ds} \left(f_\infty(\tau, H(e^{-s\mathbf{1}_B}, x)) \left(1 - e^{-s\mathbf{1}_B(x)} \right) \right) \right| \\ & \leq \mathbf{1}_B(x) e^{-s\mathbf{1}_B(x)} |f_\infty(\tau, H(e^{-s\mathbf{1}_B}, x))| + \left(1 - e^{-s\mathbf{1}_B(x)} \right) \left| \frac{d}{ds} f_\infty(\tau, H(e^{-s\mathbf{1}_B}, x)) \right| \\ & \leq \mathbf{1}_B + s\mathbf{1}_B \tau \Lambda(B) \leq \mathbf{1}_B(x) (1 + s\tau \Lambda(B)). \end{aligned}$$

In the third line, we use the inequality $1 - e^{-s\mathbf{1}_B(x)} \leq s\mathbf{1}_B(x)$. Since

$$\int_0^t \int_B (1 + s\tau \Lambda(B)) \Lambda(dx) d\tau = t\Lambda(B) + s\frac{t^2}{2} \Lambda(B)^2 < \infty,$$

we then have

$$\int_0^t \int_{\mathbb{R}^2} \left| \frac{d}{ds} \left(f_\infty(\tau, H(e^{-s\mathbf{1}_B}, x)) \left(1 - e^{-s\mathbf{1}_B(x)} \right) \right) \right| \Lambda(dx) d\tau < \infty.$$

So it is legitimate to change the order of the differentiation and the integration,

$$\begin{aligned} \int_B m_\infty(t, x) \Lambda(dx) &= \int_0^t \int_{\mathbb{R}^2} \frac{d}{ds} f_\infty(\tau, H(e^{-s\mathbf{1}_B}, x)) \left(1 - e^{-s\mathbf{1}_B(x)} \right) \Lambda(dx) d\tau \Big|_{s=0} \\ &= \int_0^t \int_B f_\infty(\tau, H(e^{-s\mathbf{1}_B}, x)) e^{-s\mathbf{1}_B(x)} \Lambda(dx) d\tau \Big|_{s=0} + \\ & \quad \int_0^t \int_B \frac{d}{ds} f_\infty(\tau, H(e^{-s\mathbf{1}_B}, x)) \left(1 - e^{-s\mathbf{1}_B(x)} \right) \Lambda(dx) d\tau \Big|_{s=0} \\ &= \int_0^t \int_B f_\infty(\tau, H(1, x)) \Lambda(dx) d\tau \\ &= \int_B \int_0^t f_\infty(\tau, H(1, x)) d\tau \Lambda(dx). \text{ (Fubini's theorem)} \end{aligned}$$

As this equality holds for any bounded measurable sets B , we must have

$$m_\infty(t, x) = \int_0^t f_\infty(\tau, H(1, x)) d\tau,$$

Λ -almost everywhere.

For $k < \infty$, by Proposition 13,

$$\frac{d}{ds} f_k(t, e^{-s\mathbf{1}_B}) \Big|_{s=0} = -m_k(t, B).$$

Moreover, by the same argument as in Proposition 7,

$$f_k(t, e^{-s\mathbf{1}_B}) = g_k(t, \mathbf{v}),$$

where $\mathbf{v} = (v_1, \dots, v_{k+1})$ with

$$\begin{aligned} v_i &= e^{-s\mathbf{1}_B \mathbf{1}_{k \in I(i)}} \text{ for } i = \overline{1, k}; \\ v_{k+1} &= e^{-s\mathbf{1}_B \mathbf{1}_{k \in J(i)}}. \end{aligned}$$

In particular, if k is even, using the notation of Theorem 3,

$$\begin{aligned} w_i &= v_{i+2} = v_i = e^{-s\mathbf{1}_B} \text{ for } i \text{ odd smaller than } k+1; \\ w_i &= v_{i-2} = v_i = 1 \text{ for } i \text{ even smaller than } k+1; \\ w_{k+1} &= v_k = 1; \\ v_{k+1} &= e^{-s\mathbf{1}_B}. \end{aligned}$$

Hence,

$$\frac{d}{dt} f_k(t, v) = - \int_{\mathbb{R}^2} g_k(t, \mathbf{H}_{k+1,k}(\mathbf{v}, x)) (1 - e^{-s\mathbf{1}_B}(x)) \Lambda(dx),$$

which is equivalent to,

$$f_k(t, v) = 1 - \int_0^t \int_{\mathbb{R}^2} g_k(\tau, \mathbf{H}_{k+1,k}(\mathbf{v}, x)) (1 - e^{-s\mathbf{1}_B}(x)) \Lambda(dx) d\tau.$$

So,

$$m_k(t, B) = \frac{d}{ds} \int_0^t \int_{\mathbb{R}^2} g_k(\tau, \mathbf{H}_{k+1,k}(\mathbf{v}, x)) (1 - e^{-s\mathbf{1}_B}(x)) \Lambda(dx) d\tau \Big|_{s=0}.$$

By an argument similar to that of the case $k = \infty$, we can change the order of the derivative and the integrations in the right hand side. As

$$\begin{aligned} & \frac{d}{ds} g_k(\tau, \mathbf{H}_{k+1,k}(\mathbf{v}, x)) (1 - e^{-s\mathbf{1}_B}(x)) \Big|_{s=0} \\ &= \frac{d}{ds} g_k(\tau, \mathbf{H}_{k+1,k}(\mathbf{v}, x)) \Big|_{s=0} (1 - e^{-s\mathbf{1}_B}(0)) - \\ & \quad g_k(\tau, \mathbf{H}_{k+1,k}(\mathbf{1}, x)) \frac{d}{ds} (1 - e^{-s\mathbf{1}_B}(x)) \Big|_{s=0} \\ &= g_k(\tau, \mathbf{H}_{k+1,k}(\mathbf{1}, x)) \mathbf{1}_B(x), \end{aligned}$$

we get

$$\int_B m_k(t, x) \Lambda(dx) = \int_0^t \int_B g_k(\tau, \mathbf{H}_{k+1,k}(\mathbf{1}, x)) \Lambda(dx) d\tau.$$

Note that $g_k(\tau, \mathbf{H}_{k+1,k}(\mathbf{1}, x)) = f_{k-1}(\tau, (1 - h(\cdot, x)))$. We get

$$\int_B m_k(t, x) \Lambda(dx) = \int_B \int_0^t f_{k-1}(\tau, (1 - h(\cdot, x))) d\tau \Lambda(dx),$$

by Fubini's theorem. This proves the proposition for k even. If k is odd,

$$\begin{aligned} w_i &= v_{i+2} = v_i = v \text{ for } i \text{ odd smaller than } k; \\ w_i &= v_{i-2} = v_i = 1 \text{ for } i \text{ even smaller than } k+1; \\ w_{k+1} &= v_{k-1} = v_{k-1} = 1; \\ w_k &= v_{k+1} = 1; \\ v_k &= v. \end{aligned}$$

By Theorem 3,

$$1 - f_k(t, v) = - \int_{\mathbb{R}^2} g_k(t, \mathbf{H}_{k,k}(\mathbf{v}, x)) (1 - e^{-s \mathbf{1}_B}) \Lambda(dx).$$

The rest of the proof in this case is similar to the case k is even, noting that $g_k(\tau, \mathbf{H}_{k,k}(\mathbf{1}, x)) = f_{k-1}(\tau, (1 - h(\cdot, x)))$ in this case. \square

7.3 Reduced Palm Probability Generating Functionals

We first derive a system of integral equations which have the Palm p.g.fl.s of the ∞ -Matérn model as a solution.

Proposition 9 *For Λ -almost every y , for every positive functions v satisfying (6.4) and every $t > 0$, the functional $f_{y,\Lambda}(t, v)$ satisfies the system of integral equations*

$$\begin{aligned} f_{y,\infty,\Lambda}(0, v) &= 1; \\ f_{y,\infty,\Lambda}(t, v) &= \frac{\int_0^t f_\Lambda(\tau, H(v, y)) d\tau}{m_{\infty,\Lambda}(t, y)} \\ &\quad - \int_0^t \int_{\mathbb{R}^2} f_{y,\infty,\Lambda}(t, H(v, x)) (1 - v(x)) (1 - h(x, y)) \frac{m_{\infty,\Lambda}(\tau, y)}{m_{\infty,\Lambda}(t, y)} \Lambda(dx) d\tau, \end{aligned}$$

where H is defined in (6.5) and $m_{\infty,\Lambda}(t, y)$ is the Radon-Nikodym derivative w.r.t. Λ of the intensity measure of $T_t(\mathcal{M}_\infty(\Phi))$ computed in Proposition 8.

Proof. See Appendix D.

As the study of the k -Matérn models p.g.fl.s requires the joint p.g.fl.s of the PPs induced by the 0-Matérn, 1-Matérn, \dots , k -Matérn models, it is natural that the study of its Palm version requires the *Palm version* of these joint p.g.fl.s. Defining such Palm joint p.g.fl.s is quite complicated in general. Nevertheless, to exemplify the idea, we present here the result for $k = \infty$ and $k = 1$.

First of all, we can assume w.l.o.g. that $u(x) > 0$ for any x in \mathbb{R}^2 (as $G_{T_t(\mathcal{M}_1(\Phi))}(v)$ is obtained by setting $u = \mathbf{1}$ in $g_{1,\Lambda}(t, v, u)$ and such u satisfies this condition). By the same arguments as in Proposition 13,

$$\begin{aligned}
& -\frac{d}{ds}g_{1,\Lambda}(t, ve^{-s\mathbf{1}_B}, u) \Big|_{s=0} \\
&= \mathbb{E} \left[T_t(\mathcal{Q}_1(\Phi))(B) \prod_{y \in T_t(\mathcal{Q}_1(\Phi))} v(y) \prod_{y \in T_t(\mathcal{R}_1(\Phi))} u(y) \right] \\
&= \mathbb{E} \left[T_t(\mathcal{M}_1(\Phi))(B) \prod_{y \in T_t(\mathcal{M}_1(\Phi))} v(y) \prod_{y \in T_t(\Phi) \setminus T_t(\mathcal{M}_1(\Phi))} u(y) \right] \\
&= \mathbb{E} \left[\sum_{x \in \mathcal{M}_1(\Phi)} \mathbf{1}_{x \in B} \prod_{y \in \mathcal{M}_1(\Phi_t)} v(y) \prod_{y \in \Phi_t} u(y) \right] \\
&= \mathbb{E} \left[\sum_{x \in T_t(\mathcal{M}_1(\Phi)) \cap B} v(x) \prod_{y \in T_t(\mathcal{M}_1(\Phi)) \setminus \{x\}} v(y) \prod_{y \in \Phi_t} u(y) \right] \\
&\leq \mathbb{E} \left[\sum_{x \in \mathcal{M}_1(\Phi_t) \cap B} v(x) \right] = \int_B v(x) m_{1,\Lambda}(t, x) \Lambda(dx).
\end{aligned}$$

The second equality comes from the fact that $\mathcal{Q}_1(\Phi) = \mathcal{M}_1(\Phi)$ and $\mathcal{R}_1(\Phi) = \Phi \setminus \mathcal{M}_1(\Phi)$. So, for each u, v , $-\frac{d}{ds}g_{1,\Lambda}(t, ve^{-s\mathbf{1}_B}, u) \Big|_{s=0}$, considered as a measure in \mathbb{R}^2 , is absolutely continuous w.r.t. $v(x)m_{1,\Lambda}(t, x)\Lambda(dx)$. Hence, it admits a Radon-Nikodym derivative w.r.t. the latter, i.e.

$$-\frac{d}{ds}g_{1,\Lambda}(t, ve^{-s\mathbf{1}_B}, u) \Big|_{s=0} = \int_B g_{x,1,\Lambda}(t, v, u) v(x) m_{1,\Lambda}(t, x) \Lambda(dx). \quad (7.3)$$

Now, by the same arguments as in Proposition 14, we can also prove that for every measurable set B not in the support of v ,

$$\frac{d}{ds}g_{1,\Lambda}(t, v + s\mathbf{1}_B, u) \Big|_{s=0} = \int_B g_{x,1,\Lambda}(t, v, u) m_{1,\Lambda}(t, x) \Lambda(dx). \quad (7.4)$$

In particular, by taking $u = \mathbf{1}$, we get:

Proposition 10 *For every x every function v satisfying (6.4),*

$$G_{x,\mathcal{M}_1(\Phi_t)}^!(v) = g_{x,1,\Lambda}(t, v, \mathbf{1}). \quad (7.5)$$

Proof. By Proposition 13 and Proposition 14,

$$\begin{aligned}
-\frac{d}{ds}g(t, ve^{-s\mathbf{1}_B}, \mathbf{1}) \Big|_{s=0} &= -\frac{d}{ds}G_{T_t(\mathcal{M}_1(\Phi))}(ve^{-s\mathbf{1}_B}) \Big|_{s=0} \\
&= \int_B v(x) G_{x, \mathcal{M}_1(\Phi_t)}^{\dagger}(v) m_{1, \Lambda}(t, x) \Lambda(dx) \\
\frac{d}{ds}g(t, v + s\mathbf{1}_B, \mathbf{1}) \Big|_{s=0} &= \frac{d}{ds}G_{T_t(\mathcal{M}_1(\Phi))}(v + s\mathbf{1}_B) \Big|_{s=0} \\
&= \int_B G_{x, \mathcal{M}_1(\Phi_t)}^{\dagger}(v) m_{1, \Lambda}(t, x) \Lambda(dx).
\end{aligned}$$

By comparing these equalities with (7.3) and (7.4), we can conclude the proof. \square

Note that the equations (7.3) and (7.4) are very similar with the result of Proposition 13, hence we can call $g_{x, \Lambda}$ the *Palm version* of the joint p.g.fl $g_{1, \Lambda}$ by abuse of notation.

We next derive a system of equations that has $g_{x, 1, \Lambda}(t, u, v)$ as a solution in the same spirit as in Proposition 9.

Proposition 11 *For Λ -almost every y , every functions $u > 0$, v satisfying (6.4), the functional $g_{y, \Lambda}$ satisfies the integral equation*

$$\begin{aligned}
g_{y, \Lambda}(0, v, u) &= 1; \\
g_{y, \Lambda}(t, v, u) &= \int_0^t \frac{g_{\Lambda}(\tau, H(v, y), H(u, y))}{m_{1, \Lambda}(t, y)} d\tau - \int_0^t \int_{\mathbb{R}^2} \left(g_{y, \Lambda}(\tau, v, u)(1 - u(x)) + \right. \\
&\quad \left. g_{y, \Lambda}(\tau, H(v, x), H(u, x))(u(x) - v(x))(1 - h(x, y)) \right) \frac{m_{1, \Lambda}(\tau, y)}{m_{1, \Lambda}(t, y)} \Lambda(dx) d\tau,
\end{aligned}$$

where H is defined in (6.5).

Proof. We present here only a sketch of this proof. To complete this sketch, it is sufficient to prove the condition for changing the order of derivatives and integrations in the same way as in the proof of Proposition 9. As there is no ambiguity, we drop the 1 and Λ subscript. By definition, for any bounded measurable B in the support of v ,

$$\frac{d}{ds}g(t, ve^{-s\mathbf{1}_B}, u) \Big|_{s=0} = - \int_B g_x(t, v, u) v(x) m(t, x) \Lambda(dx).$$

By Theorem 3,

$$\begin{aligned}
g(t, ve^{-s\mathbf{1}_B}, u) &= 1 - \int_0^t \int_{\mathbb{R}^2} g(\tau, ve^{-s\mathbf{1}_B}, u) (1 - u(x)) \Lambda(dx) d\tau - \\
&\quad \int_0^t \int_{\mathbb{R}^2} g(\tau, H(ve^{-s\mathbf{1}_B}, x), H(u, x)) (u(x) - v(x)e^{-s\mathbf{1}_B(x)}) \Lambda(dx) d\tau.
\end{aligned}$$

So,

$$\begin{aligned}
& \int_B g_x(t, v, u) v(x) m(t, x) \Lambda(dx) \\
&= \frac{d}{ds} \int_0^t \int_{\mathbb{R}^2} g_\Lambda(\tau, v e^{-s \mathbf{1}_B}, u) (1 - u(x)) \Lambda(dx) d\tau \Big|_{s=0} \\
&+ \frac{d}{ds} \int_0^t \int_{\mathbb{R}^2} g(\tau, H(v e^{-s \mathbf{1}_B}, x), H(u, x)) (u(x) - v(x) e^{-s \mathbf{1}_B(x)}) \Lambda(dx) d\tau \Big|_{s=0}.
\end{aligned}$$

The first term is

$$\begin{aligned}
& \frac{d}{ds} \int_0^t \int_{\mathbb{R}^2} g_\Lambda(\tau, v e^{-s \mathbf{1}_B}, u) (1 - u(x)) \Lambda(dx) d\tau \Big|_{s=0} \\
&= \int_0^t \int_{\mathbb{R}^2} \frac{d}{ds} g(\tau, v e^{-s \mathbf{1}_B}, u) \Big|_{s=0} (1 - u(x)) \Lambda(dx) d\tau \\
&= - \int_0^t \int_{\mathbb{R}^2} \left(\int_B g_y(\tau, v, u) v(y) m(\tau, y) \Lambda(dy) \right) (1 - u(x)) \Lambda(dx) d\tau \\
&= - \int_B \left(\int_0^t \int_{\mathbb{R}^2} g_y(\tau, v, u) (1 - u(x)) \Lambda(dx) d\tau \right) v(y) m(\tau, y) \Lambda(dy). \quad (7.6)
\end{aligned}$$

For the second term,

$$\begin{aligned}
& \frac{d}{ds} \int_0^t \int_{\mathbb{R}^2} g(\tau, H(v e^{-s \mathbf{1}_B}, x), H(u, x)) (u(x) - v(x) e^{-s \mathbf{1}_B(x)}) \Lambda(dx) d\tau \Big|_{s=0} \\
&+ \int_0^t \int_{\mathbb{R}^2} \frac{d}{ds} g(\tau, H(v e^{-s \mathbf{1}_B}, x), H(u, x)) (u(x) - v(x) e^{-s \mathbf{1}_B(x)}) \Big|_{s=0} \Lambda(dx) d\tau \\
&= \int_0^t \int_{\mathbb{R}^2} \frac{d}{ds} g(\tau, H(v e^{-s \mathbf{1}_B}, x), H(u, x)) \Big|_{s=0} (u(x) - v(x) e^{-s \mathbf{1}_B(x)}) \Big|_{s=0} \Lambda(dx) d\tau \\
&+ \int_0^t \int_{\mathbb{R}^2} g(\tau, H(v e^{-s \mathbf{1}_B}, x), H(u, x)) \Big|_{s=0} \frac{d}{ds} (u(x) - v(x) e^{-s \mathbf{1}_B(x)}) \Big|_{s=0} \Lambda(dx) d\tau.
\end{aligned}$$

The second term in the above equality is

$$\begin{aligned}
& \int_0^t \int_{\mathbb{R}^2} g(\tau, H(v e^{-s \mathbf{1}_B}, x), H(u, x)) \Big|_{s=0} \frac{d}{ds} (u(x) - v(x) e^{-s \mathbf{1}_B(x)}) \Big|_{s=0} \Lambda(dx) d\tau \\
&= \int_0^t \int_{\mathbb{R}^2} g(\tau, v, H(u, x)) v(x) \mathbf{1}_B(x) \Lambda(dx) d\tau \\
&= \int_B \int_0^t g(\tau, H(v, x), H(u, y)) v(y) d\tau \Lambda(dy), \quad (7.7)
\end{aligned}$$

while the first term is

$$\begin{aligned}
& \int_0^t \int_{\mathbb{R}^2} \frac{d}{ds} g(\tau, H(v e^{-s \mathbf{1}_B}, x), H(u, x)) \Big|_{s=0} \left(u(x) - v(x) e^{-s \mathbf{1}_B(x)} \right) \Big|_{s=0} \Lambda(dx) d\tau \\
&= - \int_0^t \int_{\mathbb{R}^2} \int_B g_y(\tau, H(v, x), H(u, x)) H(v, x)(y) m(\tau, y) \Lambda(dy) (u(x) - v(x)) \\
&\quad \Lambda(dx) d\tau \\
&= - \int_0^t \int_{\mathbb{R}^2} \int_B g_y(\tau, H(v, x), H(u, x)) (1 - h(x, y)) v(y) m(\tau, y) \Lambda(dy) \\
&\quad (u(x) - v(x)) \Lambda(dx) d\tau \\
&= - \int_B \left(\int_0^t \int_{\mathbb{R}^2} g_y(\tau, H(v, x), H(u, x)) (u(x) - v(x)) (1 - h(x, y)) \Lambda(dx) d\tau \right) \\
&\quad v(y) m(\tau, y) \Lambda(dy). \tag{7.8}
\end{aligned}$$

Putting together (7.6), (7.7) and (7.8), we get

$$\begin{aligned}
& \int_B g_y(t, v, u) v(y) m(t, y) \Lambda(dy) = \int_B \int_0^t g(\tau, H(v, x), H(u, y)) v(y) d\tau \Lambda(dy) \\
& - \int_B \left(\int_0^t \int_{\mathbb{R}^2} g_y(\tau, v, u) (1 - u(x)) \Lambda(dx) d\tau \right) v(y) m(\tau, y) \Lambda(dy) - \int_B \left(\int_0^t \int_{\mathbb{R}^2} g_y(\tau, H(v, x), H(u, x)) (u(x) - v(x)) (1 - h(x, y)) \Lambda(dx) d\tau \right) v(y) m(\tau, y) \Lambda(dy)
\end{aligned}$$

for every bounded measurable B in the support of v , which proves the proposition for Λ -almost every x such that $v(x) > 0$. For x such that $v(x) = 0$, proceed as above and use the equality

$$\frac{d}{ds} g(t, v + s \mathbf{1}_B, u) \Big|_{s=0} = \int_B g_x(t, v, u) m(t, x) \Lambda(dx).$$

for every bounded measurable B not in the support of v . \square

Remarks: Note that the method used in this section can be extended to compute the n^{th} -moment measures and the n^{th} -fold Palm distribution of the PPs induced by the Matérn models. In particular, the n^{th} moment measure is the n^{th} derivative of the p.g.f.s at 0 for a suitably chosen function v . Thus, by using Theorems 2 and 3, we can compute these measures by an induction argument on n . Then, by using the same argument but with a general function v , we can derive a system of integral equations that has the n^{th} -fold Palm p.g.f.s as solutions. These computations are, however, long and tedious and are hence omitted here.

Acknowledgment

The authors would like to thank D. Daley for his very valuable comments on this work. The early stages of this work were initiated in France at Ecole Normale Supérieure and INRIA, The later stages were pursued in the USA at Qualcomm for the first author and at the University of Texas at Austin for the second author, where they were supported by a grant of the Simons Foundation (#197982 to UT Austin).

A Palm version of Probability Generating Functionals

We define the Palm version and the reduced Palm version of the p.g.f.s of a PP N as

$$G_{x,N}(v) := \mathbb{E}_{x,N} \left[\prod_{y \in N} v(y) \right]; \quad (\text{A.1})$$

$$G_{x,N}^!(v) := \mathbb{E}_{x,N}^! \left[\prod_{y \in N} v(y) \right], \quad (\text{A.2})$$

where $\mathbb{E}_{x,N}$ and $\mathbb{E}_{x,N}^!$ are the Palm distribution and the reduced Palm distribution of N , respectively. The relation between the reduced Palm version and the Palm version is characterized as follows.

Proposition 12 *For any PP N with intensity measure m_N , we have for m_N -almost every x ,*

$$G_{x,N}(v) = v(x) G_{x,N}^!(v). \quad (\text{A.3})$$

Proof Let $f(x, N) = \prod_{y \in N} v(y)$ and $g(x, N) = v(x) \prod_{y \in N} v(y)$. We have for any $x \in N$,

$$f(x, N) = v(x) f(x, N \setminus x) = g(x, N \setminus x).$$

So,

$$\begin{aligned} \int_{\mathbb{R}^2} \mathbb{E}_x [f(x, N)] m_N(dx) &= \mathbb{E} \left[\sum_{x \in N} f(x, N) \right] \\ &= \mathbb{E} \left[\sum_{x \in N} g(x, N \setminus x) \right] \\ &= \int_{\mathbb{R}^d} \mathbb{E}_x^! [g(x, N)] m_N(dx) \\ &= \int_{\mathbb{R}^d} \mathbb{E}_x^! [v(x) f(x, N)] m_N(dx) \\ &= \int_{\mathbb{R}^d} v(x) \mathbb{E}_x^! [f(x, N)] m_N(dx). \end{aligned}$$

The conclusion then follows directly. \square

Hence, we can write

$$G_{x,N}^!(v) := \mathbb{E}_{x,N}^! \left[\prod_{y \in N} v(y) \right] = \mathbb{E}_{x,N}^! \left[\prod_{y \in N \setminus \{x\}} v(y) \right]. \quad (\text{A.4})$$

And moreover, it is now sufficient to concentrate on the reduced Palm p.g.fl.s. The next two results give us the relation between the Palm and non Palm versions of the p.g.fl of a PP.

Proposition 13 *Let N be a PP with locally finite intensity measure. Then for any function v and any bounded measurable set B ,*

$$\begin{aligned}\frac{d}{dt}G_N(v e^{-t\mathbf{1}_B}) &= - \int_B G_{x,N}(v e^{-t\mathbf{1}_B}) m_N(dx) \\ &= - \int_B v(x) e^{-t\mathbf{1}_B(x)} G_{x,N}^!(v e^{-t\mathbf{1}_B}) m_N(dx).\end{aligned}\quad (\text{A.5})$$

Proof. We have,

$$\begin{aligned}\frac{d}{dt} \left(\prod_{x \in N} v(x) e^{-t\mathbf{1}_B(x)} \right) &= \frac{d}{dt} \left(\prod_{x \in N} v(x) \right) e^{-tN(B)} \\ &= - \left(\prod_{x \in N} v(x) \right) e^{-tN(B)} N(B) \\ &= - \left(\prod_{x \in N} v(x) e^{-t\mathbf{1}_B(x)} \right) N(B) \\ &= - \sum_{x \in B \cap N} \left(\prod_{y \in N} v(y) e^{-t\mathbf{1}_B(y)} \right).\end{aligned}$$

Since the absolute value of the last line is bounded above by $N(B)$ and $\mathbb{E}[N(B)] = m_N(B) < \infty$ by definition, we have by bounded convergence theorem,

$$\begin{aligned}\frac{d}{dt}G_N(v e^{-t\mathbf{1}_B}) &= \frac{d}{dt} \mathbb{E} \left[\left(\prod_{x \in N} v(x) e^{-t\mathbf{1}_B(x)} \right) \right] \\ &= \mathbb{E} \left[\frac{d}{dt} \left(\prod_{x \in N} v(x) e^{-t\mathbf{1}_B(x)} \right) \right] \\ &= - \mathbb{E} \left[\sum_{x \in B \cap N} \left(\prod_{y \in N} v(y) e^{-t\mathbf{1}_B(y)} \right) \right].\end{aligned}$$

As the last line is equal to $-\int_B G_{x,N}(v e^{-t\mathbf{1}_B}) m_N(dx)$ by the Campbell formula, the conclusion follows directly. \square

However, the previous proposition does not give us the relation between the p.g.fl and its reduced Palm versions at x such that $v(x) = 0$. For such x , we need the following result.

Proposition 14 *Let N be a PP with locally finite intensity measure and t be positive number smaller than 1. For any function v and any measurable set B not in the support of v (i.e. $v(x) = 0$ for every x in B),*

$$\frac{d}{dt}G_N(v + t\mathbf{1}_B) = \int_B G_{x,N}^!(v + t\mathbf{1}_B)m_N(dx). \quad (\text{A.6})$$

Proof. Since B is not in the support of v ,

$$\begin{aligned} \frac{d}{dt} \left(\prod_{y \in N} (v(y) + \mathbf{1}_B(y)) \right) &= \frac{d}{dt} \left(\prod_{y \in N \setminus B} v(y) \right) t^{N(B)} \\ &= \left(\prod_{y \in N \setminus B} v(y) \right) t^{N(B)-1} N(B) \\ &= \left(\prod_{y \in N \setminus B} v(y) \right) \left(\sum_{x \in N \cap B} \prod_{y \in (N \cap B) \setminus \{x\}} t \right) \\ &= \sum_{x \in N \cap B} \left(\prod_{y \in N \setminus B} v(y) \prod_{y \in N \cap B \setminus \{x\}} t \right) \\ &= \sum_{x \in N \cap B} \left(\prod_{y \in N \setminus \{x\}} (v(y) + \mathbf{1}_B(y)) \right). \end{aligned}$$

Again, by bounded convergence theorem,

$$\begin{aligned} \frac{d}{dt}G_N(v + t\mathbf{1}_B) &= \mathbb{E} \left[\frac{d}{dt} \left(\prod_{y \in N} (v(y) + \mathbf{1}_B(y)) \right) \right] \\ &= \mathbb{E} \left[\sum_{x \in N \cap B} \left(\prod_{y \in N \setminus \{x\}} (v(y) + \mathbf{1}_B(y)) \right) \right]. \end{aligned}$$

The conclusion follows directly from the fact that the last line equals

$$\int_B G_{x,N}^!(v + t\mathbf{1}_B)m_N(dx)$$

by reduced Campbell formula. □

B Proof of Lemma 2

Every expectation in this proof should be understood as the conditional expectation given Φ_t . By Lemma 1,

$$\prod_{x \in T_{t,t+\epsilon}(\mathcal{M}_\infty(\Phi))} v(x) = 1 + \sum_{i=1}^{\infty} (-1)^i \sum_{(x_1, \dots, x_i) \in (T_{t,t+\epsilon}(\mathcal{M}_\infty(\Phi)))^{(i!)}} \prod_{j=1}^i (1 - v(x_j)).$$

The first step is to show that for ϵ small enough,

$$\left| \mathbb{E} \left[\sum_{i=2}^{\infty} \sum_{(x_1, \dots, x_i) \in (T_{t,t+\epsilon}(\mathcal{M}_\infty(\Phi)))^{(i!)}} \prod_{j=1}^i (1 - v(x_j)) \right] \right| \leq 2\epsilon^2 \left(\int_{\mathbb{R}^2} (1 - v(x)) \Lambda(dx) \right)^2 \quad \text{a.s.}$$

Since $T_{t,t+\epsilon}(\mathcal{M}_\infty(\Phi)) \subseteq T_{t,t+\epsilon}(\Phi)$ a.s.,

$$\begin{aligned} & \left| \mathbb{E} \left[\sum_{i=2}^{\infty} \sum_{(x_1, \dots, x_i) \in (T_{t,t+\epsilon}(\mathcal{M}_\infty(\Phi)))^{(i!)}} \prod_{j=1}^i (1 - v(x_j)) \right] \right| \\ & \leq \mathbb{E} \left[\sum_{i=2}^{\infty} \sum_{(x_1, \dots, x_i) \in (T_{t,t+\epsilon}(\Phi))^{(i!)}} \prod_{j=1}^i (1 - v(x_j)) \right] \\ & = \sum_{i=2}^{\infty} \mathbb{E} \left[\sum_{(x_1, \dots, x_i) \in (T_{t,t+\epsilon}(\Phi))^{(i!)}} \prod_{j=1}^i (1 - v(x_j)) \right] \\ & = \sum_{i=2}^{\infty} \epsilon^i \left(\int_{\mathbb{R}^2} (1 - v(x)) \Lambda(dx) \right)^i \quad \text{a.s.}, \end{aligned}$$

where in the last line we apply the multivariate Campbell formula to the PPP $T_{t,t+\epsilon}(\Phi)$ [16, p.112]. Take now any $\epsilon < \frac{1}{2} \left(\int_{\mathbb{R}^2} (1 - v(x)) \Lambda(dx) \right)^{-1}$,

$$\begin{aligned} \sum_{i=2}^{\infty} \epsilon^i \left(\int_{\mathbb{R}^2} (1 - v(x)) \Lambda(dx) \right)^i &= \epsilon^2 \frac{\left(\int_{\mathbb{R}^2} (1 - v(x)) \Lambda(dx) \right)^2}{1 - \epsilon \int_{\mathbb{R}^2} (1 - v(x)) \Lambda(dx)} \\ &\leq 2\epsilon^2 \left(\int_{\mathbb{R}^2} (1 - v(x)) \Lambda(dx) \right)^2. \end{aligned}$$

The next step is to bound $\mathbb{E} \left[\sum_{x \in T_{t,t+\epsilon}(\mathcal{M}_\infty(\Phi))} (1 - v(x)) \right]$. By Proposition 5,

$$\Delta_{\infty,d,t,t+\epsilon} \subseteq T_{t,t+\epsilon}(\mathcal{M}_\infty(\Phi)) \subseteq \Delta_{\infty,u,t,t+\epsilon} \quad \text{a.s.}$$

Then,

$$\sum_{x \in \Delta_{\infty, d, t, t+\epsilon}} (1 - v(x)) \leq \sum_{x \in T_{t, t+\epsilon}(\mathcal{M}_{\infty}(\Phi))} (1 - v(x)) \leq \sum_{x \in \Delta_{\infty, u, t, t+\epsilon}} (1 - v(x)) \text{ a.s.}$$

Given Φ_t , $\Delta_{\infty, u, t, t+\epsilon}$ is an independently thinning of $T_{t, t+\epsilon}(\Phi)$ with thinning probability $\prod_{y \in T_t(\mathcal{M}_{\infty}(\Phi))} (1 - h(x, y))$. Hence, it is a PPP of intensity $\epsilon \Lambda_{\infty, t}$. We have then,

$$\mathbb{E} \left[\sum_{x \in \Delta_{\infty, u, t, t+\epsilon}} (1 - v(x)) \right] = \epsilon \int_{\mathbb{R}^2} (1 - v(x)) \Lambda_{\infty, t}(dx) \text{ a.s.} \quad (\text{B.1})$$

Moreover, we can compute the intensity of $\Delta_{\infty, d, t, t+\epsilon}$ (conditioned on Φ_t) as follow. Take any bounded measurable set A in \mathbb{R}^2 ,

$$\begin{aligned} & \mathbb{E} [|\Delta_{\infty, d, t, t+\epsilon} \cap A|] \\ &= \mathbb{E} \left[\sum_{x \in T_{t, t+\epsilon}(\Phi) \cap A} \left(\left(\prod_{y \in T_{t, t+\epsilon}(\Phi)} \mathbf{1}_{C(x, y)=0} \right) \left(\prod_{y \in T_t(\mathcal{M}_{\infty}(\Phi))} \mathbf{1}_{C(x, y)=0} \right) \right) \right] \\ &= \mathbb{E} \left[\sum_{x \in T_{t, t+\epsilon}(\Phi) \cap A} \left(\left(\prod_{y \in T_{t, t+\epsilon}(\Phi)} \mathbf{1}_{C(x, y)=0} \right) \left(\prod_{y \in T_t(\mathcal{M}_{\infty}(\Phi))} (1 - h(x, y)) \right) \right) \right]. \end{aligned}$$

Let $\mathbb{P}_x^!$ be the *reduced Palm* distribution of $T_{t, t+\epsilon}(\Phi)$ given a point at x . By Slivnyak's theorem, this reduced Palm distribution is the distribution of a PPP of intensity measure $\epsilon \Lambda$. Moreover, as $T_{t, t+\epsilon}(\Phi)$ is independent with $T_t(\mathcal{M}_{\infty}(\Phi))$, its Palm distribution is also independent with the latter. Hence, by the refined Campbell formula,

$$\begin{aligned} & \mathbb{E} [|\Delta_{\infty, d, t, t+\epsilon} \cap A|] \\ &= \epsilon \int_A \mathbb{E}_x^! \left[\prod_{y \in T_{t, t+\epsilon}(\Phi)} \mathbf{1}_{C(x, y)=0} \right] \prod_{y \in T_t(\mathcal{M}_{\infty}(\Phi))} \mathbf{1}_{C(x, y)=0} \Lambda(dx) \\ &= \epsilon \int_A \mathbb{E}_x^! \left[\prod_{y \in T_{t, t+\epsilon}(\Phi)} (1 - h(x, y)) \right] \prod_{y \in T_t(\mathcal{M}_{\infty}(\Phi))} (1 - h(x, y)) \Lambda(dx) \\ &= \epsilon \int_A \exp \left\{ -\epsilon \int_{\mathbb{R}^2} h(x, y) \Lambda(dy) \right\} \Lambda_{\infty, t}(dx). \end{aligned}$$

Thus, the intensity measure of $\Delta_{\infty, d, t, t+\epsilon}$ is

$$\epsilon \exp \left\{ -\epsilon \int_{\mathbb{R}^2} h(x, y) \Lambda(dy) \right\} \Lambda_{\infty, t}(dx).$$

We now apply Campbell's formula to $\Delta_{\infty, d, t, t+\epsilon}$,

$$\mathbb{E} \left[\sum_{x \in \Delta_{\infty, d, t, t+\epsilon}} (1 - v(x)) \right] = \epsilon \int_{\mathbb{R}^2} (1 - v(x)) \exp \left\{ -\epsilon \int_{\mathbb{R}^2} h(x, y) \Lambda(dy) \right\} \Lambda_{\infty, t}(dx).$$

As

$$\exp \left\{ -\epsilon \int_{\mathbb{R}^2} h(x, y) \Lambda(dy) \right\} \geq 1 - \epsilon \int_{\mathbb{R}^2} h(x, y) \Lambda(dy) \geq 1 - \epsilon \overline{H},$$

we get

$$\begin{aligned} \epsilon \int_{\mathbb{R}^2} (1 - v(x)) \Lambda_{\infty, t}(dx) &\geq \mathbb{E} \left[\sum_{x \in T_{t, t+\epsilon}(\mathcal{M}_{\infty}(\Phi))} (1 - v(x)) \right] \\ &\geq \epsilon \int_{\mathbb{R}^2} (1 - v(x)) \Lambda_{\infty, t}(dx) - \epsilon^2 \overline{H} \int_{\mathbb{R}^2} (1 - v(x)) \Lambda_{\infty, t}(dx) \\ &\geq \epsilon \int_{\mathbb{R}^2} (1 - v(x)) \Lambda_{\infty, t}(dx) - \epsilon^2 \overline{H} \left(\int_{\mathbb{R}^2} (1 - v(x)) \Lambda(dx) \right) \text{ a.s.} \end{aligned} \quad (\text{B.2})$$

The conclusion then follows directly by putting together (B.1) and (B.2).

C Proof of Theorem 3

The proof that $g_{k, \Lambda}$ is continuous in t is similar to the proof of Proposition 6. For the second part, following the same method as in the proof of Theorem 2, we compute the conditional expectation

$$\mathbb{E} \left[\left(\prod_{i=1}^k \left(\prod_{x \in T_{t, t+\epsilon}(\mathcal{Q}_i(\Phi))} v_i(x) \right) \right) \left(\prod_{x \in T_{t, t+\epsilon}(\mathcal{R}_k(\Phi))} v_{k+1}(x) \right) - 1 \middle| T_t(\Phi) \right].$$

To avoid cumbersome notation, we write \mathbb{E}_t for the conditional expectation given $T_t(\Phi)$. By the same bounding technique as in Lemma 2, we get

$$\begin{aligned} &\left| 1 - \mathbb{E}_t \left[\left(\prod_{i=1}^k \left(\prod_{x \in T_{t, t+\epsilon}(\mathcal{Q}_i(\Phi))} v_i(x) \right) \right) \left(\prod_{x \in T_{t, t+\epsilon}(\mathcal{R}_k(\Phi))} v_{k+1}(x) \right) - 1 \right] \right| + \\ &\sum_{i=1}^k \mathbb{E}_t \left[\sum_{x \in T_{t, t+\epsilon}(\mathcal{Q}_i(\Phi))} (1 - v_i(x)) \right] + \mathbb{E}_t \left[\sum_{x \in T_{t, t+\epsilon}(\mathcal{R}_k(\Phi))} (1 - v_{k+1}(x)) \right] \Bigg| \\ &\leq \sum_{i=2}^{\infty} \mathbb{E}_t \left[\sum_{x_1, \dots, x_i \text{ mutually different in } T_{t, t+\epsilon}(\Phi)} \prod_{j=1}^i (1 - v_{\min}(x_j)) \right] \\ &= \sum_{i=2}^{\infty} \left(\int_{\mathbb{R}^2} (1 - v_{\min}(x)) \epsilon \Lambda(dx) \right)^i \leq 2\epsilon^2 \left(\int_{\mathbb{R}^2} (1 - v_{\min}(x)) \Lambda(dx) \right) \text{ a.s.}, \end{aligned}$$

where $v_{\min}(x) = \min_{i=1, \dots, k+1} (v_i(x))$ and ϵ small enough. In particular, one can take any ϵ smaller than $(2 \int_{\mathbb{R}^2} (1 - v_{\min}(x)) \Lambda(dx))^{-1}$ to get

$$\left| 1 - \mathbb{E}_t \left[\left(\prod_{i=1}^k \left(\prod_{x \in T_{t,t+\epsilon}(\mathcal{Q}_i(\Phi))} v_i(x) \right) \right) \left(\prod_{x \in T_{t,t+\epsilon}(\mathcal{R}_k(\Phi))} v_k(x) \right) - 1 \right] + \sum_{i=1}^k \mathbb{E}_t \left[\sum_{x \in T_{t,t+\epsilon}(\mathcal{Q}_i(\Phi))} (1 - v_i(x)) \right] + \mathbb{E}_t \left[\sum_{x \in T_{t,t+\epsilon}(\mathcal{R}_k(\Phi))} (1 - v_{k+1}(x)) \right] \right| \leq \epsilon \quad (\text{C.1})$$

We now bound $\mathbb{E}_t \left[\sum_{x \in T_{t,t+\epsilon}(\mathcal{Q}_i(\Phi))} (1 - v(x)) \right]$ and $\mathbb{E}_t \left[\sum_{x \in T_{t,t+\epsilon}(\mathcal{R}_i(\Phi))} (1 - v(x)) \right]$ with v any function taking value in $[0, 1]$ and satisfying (6.2). We start with the case where i is even, i.e. $i = 2j$. First note that $\mathcal{Q}_{2j}(\Phi) = \mathcal{M}_{2j-2}(\Phi) \setminus \mathcal{M}_{2j}(\Phi)$ and $\mathcal{R}_{2j}(\Phi) = \mathcal{M}_{2j}(\Phi) \setminus \mathcal{M}_{2j-1}(\Phi)$ a.s. Hence,

$$\begin{aligned} & \mathbb{E}_t \left[\sum_{x \in T_{t,t+\epsilon}(\mathcal{Q}_{2j}(\Phi))} (1 - v(x)) \right] \\ &= \mathbb{E}_t \left[\sum_{x \in T_{t,t+\epsilon}(\mathcal{M}_{2j-2}(\Phi))} (1 - v(x)) \right] - \mathbb{E}_t \left[\sum_{x \in T_{t,t+\epsilon}(\mathcal{M}_{2j}(\Phi))} (1 - v(x)) \right]; \\ & \mathbb{E}_t \left[\sum_{x \in T_{t,t+\epsilon}(\mathcal{R}_{2j}(\Phi))} (1 - v(x)) \right] \\ &= \mathbb{E}_t \left[\sum_{x \in T_{t,t+\epsilon}(\mathcal{M}_{2j}(\Phi))} (1 - v(x)) \right] - \mathbb{E}_t \left[\sum_{x \in T_{t,t+\epsilon}(\mathcal{M}_{2j-1}(\Phi))} (1 - v(x)) \right] \text{ a.s..} \end{aligned}$$

By Proposition 5, we have that $\Delta_{i,d,t,\epsilon} \subseteq T_{t,t+\epsilon}(\mathcal{M}_i(\Phi)) \subseteq \Delta_{i,u,t,\epsilon}$ for every

positive integer i a.s. Hence,

$$\begin{aligned}
& \mathbb{E}_t \left[\sum_{x \in \Delta_{2j-2, u, t, \epsilon}} (1 - v(x)) \right] - \mathbb{E}_t \left[\sum_{x \in \Delta_{2j, d, t, \epsilon}} (1 - v(x)) \right] \\
& \geq \mathbb{E}_t \left[\sum_{x \in T_{t, t+\epsilon}(\mathcal{Q}_{2j}(\Phi))} (1 - v(x)) \right] \\
& \geq \mathbb{E}_t \left[\sum_{x \in \Delta_{2j-2, d, t, \epsilon}} (1 - v(x)) \right] - \mathbb{E}_t \left[\sum_{x \in \Delta_{2j, u, t, \epsilon}} (1 - v(x)) \right]; \\
& \mathbb{E}_t \left[\sum_{x \in \Delta_{2j, u, t, \epsilon}} (1 - v(x)) \right] - \mathbb{E}_t \left[\sum_{x \in \Delta_{2j-1, d, t, \epsilon}} (1 - v(x)) \right] \\
& \geq \mathbb{E}_t \left[\sum_{x \in T_{t, t+\epsilon}(\mathcal{R}_{2j}(\Phi))} (1 - v(x)) \right] \\
& \geq \mathbb{E}_t \left[\sum_{x \in \Delta_{2j, d, t, \epsilon}} (1 - v(x)) \right] - \mathbb{E}_t \left[\sum_{x \in \Delta_{2j-1, u, t, \epsilon}} (1 - v(x)) \right] \text{ a.s.}
\end{aligned}$$

We now compute $\mathbb{E}_t \left[\sum_{x \in \Delta_{i, u, t, \epsilon}} (1 - v(x)) \right]$ and bound $\mathbb{E}_t \left[\sum_{x \in \Delta_{i, d, t, \epsilon}} (1 - v(x)) \right]$. This is done by following the same bounding method in the proof of Lemma 2,

$$\begin{aligned}
\mathbb{E}_t \left[\sum_{x \in \Delta_{i, u, t, \epsilon}} (1 - v(x)) \right] &= \epsilon \int_{\mathbb{R}^2} (1 - v(x)) \Lambda_{i, t}(dx); \\
\mathbb{E}_t \left[\sum_{x \in \Delta_{i, d, t, \epsilon}} (1 - v(x)) \right] &= \epsilon \int_{\mathbb{R}^2} (1 - v(x)) e^{-\epsilon \overline{H}} \Lambda_{i, t}(dx) \\
&\geq \epsilon \int_{\mathbb{R}^2} (1 - v(x)) (1 - \epsilon \overline{H}) \Lambda_{i, t}(dx) \\
&\geq \epsilon \int_{\mathbb{R}^2} (1 - v(x)) \Lambda_{i, t}(dx) - \epsilon^2 \overline{H} \int_{\mathbb{R}^2} (1 - v(x)) \Lambda(dx) \text{ a.s.},
\end{aligned}$$

where $\Lambda_{i, t}(dx) = \prod_{y \in T_t(\mathcal{M}_{i-1}(\Phi))} (1 - h(x, y)) \Lambda(dx)$. The last inequality comes

from the fact that $\Lambda_{i,t}$ is smaller than Λ almost everywhere. So,

$$\begin{aligned}
& \epsilon \int_{\mathbb{R}^2} (1 - v(x)) (\Lambda_{2j-2,t} - \Lambda_{2j,t})(dx) + \epsilon^2 \overline{H} \int_{\mathbb{R}^2} (1 - v(x)) \Lambda(dx) \\
& \geq \mathbb{E}_t \left[\sum_{x \in T_{t,t+\epsilon}(\mathcal{Q}_{2j}(\Phi))} (1 - v(x)) \right] \\
& \geq \epsilon \int_{\mathbb{R}^2} (1 - v(x)) (\Lambda_{2j-2,t} - \Lambda_{2j,t})(dx) - \epsilon^2 \overline{H} \int_{\mathbb{R}^2} (1 - v(x)) \Lambda(dx); \\
& \epsilon \int_{\mathbb{R}^2} (1 - v(x)) (\Lambda_{2j,t} - \Lambda_{2j-1,t})(dx) + \epsilon^2 \overline{H} \int_{\mathbb{R}^2} (1 - v(x)) \Lambda(dx) \\
& \geq \mathbb{E} \left[\sum_{x \in T_{t,t+\epsilon}(\mathcal{R}_{2j}(\Phi))} (1 - v(x)) \right] \\
& \geq \epsilon \int_{\mathbb{R}^2} (1 - v(x)) (\Lambda_{2j,t} - \Lambda_{2j-1,t})(dx) - \epsilon^2 \overline{H} \int_{\mathbb{R}^2} (1 - v(x)) \Lambda(dx).
\end{aligned}$$

Doing similarly for the second case where $i = 2j - 1$, we get

$$\begin{aligned}
& \epsilon \int_{\mathbb{R}^2} (1 - v(x)) (\Lambda_{2j-1,t} - \Lambda_{2j-3,t})(x) + \epsilon^2 \overline{H} \int_{\mathbb{R}^2} (1 - v(x)) \Lambda(dx) \\
& \geq \mathbb{E}_t \left[\sum_{x \in T_{t,t+\epsilon}(\mathcal{Q}_{2j-1}(\Phi))} (1 - v(x)) \right] \\
& \epsilon \int_{\mathbb{R}^2} (1 - v(x)) (\Lambda_{2j-1,t} - \Lambda_{2j-3,t})(x) - \epsilon^2 \overline{H} \int_{\mathbb{R}^2} (1 - v(x)) \Lambda(dx) \\
& \epsilon \int_{\mathbb{R}^2} (1 - v(x)) (\Lambda_{2j-2,t} - \Lambda_{2j-1,t})(x) + \epsilon^2 \overline{H} \int_{\mathbb{R}^2} (1 - v(x)) \Lambda(dx) \\
& \geq \mathbb{E}_t \left[\sum_{x \in T_{t,t+\epsilon}(\mathcal{R}_{2j-1}(\Phi))} (1 - v(x)) \right] \\
& \epsilon \int_{\mathbb{R}^2} (1 - v(x)) (\Lambda_{2j-2,t} - \Lambda_{2j-1,t})(x) - \epsilon^2 \overline{H} \int_{\mathbb{R}^2} (1 - v(x)) \Lambda(dx).
\end{aligned}$$

Note that in the above formula, $\Lambda_{-1}(dx) = 0$ by convention. So,

$$\begin{aligned}
& - \lim_{\epsilon \rightarrow 0} \epsilon^{-1} \mathbb{E}_t \left[\left(\prod_{i=1}^{2k} \left(\prod_{x \in T_{t,t+\epsilon}(\mathcal{Q}_i(\Phi))} v_i(x) \right) \right) \left(\prod_{x \in T_{t,t+\epsilon}(\mathcal{R}_{2k}(\Phi))} v_{2k+1}(x) \right) - 1 \right] \\
& = \int_{\mathbb{R}^2} (1 - v_{2k+1}(x)) (\Lambda_{2k,t} - \Lambda_{2k-1,t})(dx) + \sum_{j=1}^k (1 - v_{2j-1}(x)) (\Lambda_{2j-1,t} - \Lambda_{2j-3,t})(dx) \\
& \quad + \sum_{j=1}^k \int_{\mathbb{R}^2} (1 - v_{2j}(x)) (\Lambda_{2j-2,t} - \Lambda_{2j,t})(dx) \\
& = \sum_{j=1}^k \int_{\mathbb{R}^2} (v_{2j+1}(x) - v_{2j-1}(x)) \Lambda_{2j-1,t}(dx) + \sum_{j=1}^k \int_{\mathbb{R}^2} (v_{2j}(x) - v_{2j+2}(x)) \Lambda_{2j,t}(dx) \\
& = \sum_{i=1}^{2k} (w_i(x) - v_i(x)) \Lambda_{i,t}(dx); \tag{C.2}
\end{aligned}$$

and

$$\begin{aligned}
& - \lim_{\epsilon \rightarrow 0} \epsilon^{-1} \mathbb{E}_t \left[\left(\prod_{i=1}^{2k-1} \left(\prod_{x \in T_{t,t+\epsilon}(\mathcal{Q}_i(\Phi))} v_i(x) \right) \right) \left(\prod_{x \in T_{t,t+\epsilon}(\mathcal{R}_{2k-1}(\Phi))} v_{2k}(x) \right) - 1 \right] \\
& = \int_{\mathbb{R}^2} (1 - v_{2k}(x)) (\Lambda_{2k-2,t} - \Lambda_{2k-1,t})(dx) + \sum_{j=1}^k \int_{\mathbb{R}^2} (1 - v_{2j-1}(x)) (\Lambda_{2j-1,t} - \Lambda_{2j-3,t})(dx) \\
& \quad + \sum_{j=1}^{k-1} \int_{\mathbb{R}^2} (1 - v_{2j}(x)) (\Lambda_{2j-2,t} - \Lambda_{2j,t})(dx) \\
& = \sum_{j=1}^{k-1} \int_{\mathbb{R}^2} (v_{2j+1}(x) - v_{2j-1}(x)) \Lambda_{2j-1,t}(dx) + \sum_{j=1}^{k-1} \int_{\mathbb{R}^2} (v_{2j}(x) - v_{2j+2}(x)) \Lambda_{2j,t}(dx) \\
& = \sum_{i=1}^{2k+1} (w_i(x) - v_i(x)) \Lambda_{i,t}(dx) \text{ a.s.} \tag{C.3}
\end{aligned}$$

By noting that

$$\mathcal{M}_i(\Phi) = \left(\bigcup_{k \geq j \geq 1, i \in I_j} \mathcal{Q}_j(\Phi) \right) \cup \mathcal{R}_k(\Phi)$$

if $i \in J_k$ and

$$\mathcal{M}_i(\Phi) = \left(\bigcup_{k \geq j \geq 1, i \in I_j} \mathcal{Q}_j(\Phi) \right)$$

otherwise, we have

$$\begin{aligned}
& \mathbb{E} \left[\left(\prod_{j=1}^k \left(\prod_{y \in T_t(\mathcal{Q}_j(\Phi))} v_j(y) \right) \right) \left(\prod_{y \in T_t(\mathcal{R}_k(\Phi))} v_{k+1}(y) \right) \Lambda_{i,t}(dx) \right] \\
&= \mathbb{E} \left[\left(\prod_{j=1}^k \left(\prod_{y \in T_t(\mathcal{Q}_j(\Phi))} v_j(y) \right) \right) \left(\prod_{y \in T_t(\mathcal{R}_k(\Phi))} v_{k+1}(y) \right) \right. \\
&\quad \left. \left(\prod_{y \in T_t(\mathcal{M}_{i-1}(\Phi))} (1 - h(x, y)) \right) \Lambda(dx) \right] \\
&= \mathbb{E} \left[\left(\prod_{j=1}^k \left(\prod_{y \in T_t(\mathcal{Q}_j(\Phi))} v_j(y) \right) \right) \left(\prod_{y \in T_t(\mathcal{R}_k(\Phi))} v_{k+1}(y) \right) \right. \\
&\quad \left. \left(\prod_{k \geq j \geq 1, i-1 \in I_j} \left(\prod_{y \in T_t(\mathcal{Q}_j(\Phi))} (1 - h(x, y)) \right) \prod_{y \in T_t(\mathcal{R}_k(\Phi))} (1 - h(x, y)) \right) \right] \Lambda(dx) \\
&= \mathbb{E} \left[\left(\prod_{j=1}^k \left(\prod_{y \in T_t(\mathcal{Q}_j(\Phi))} \mathbf{u}_{j,i,k}(y, x) \right) \right) \left(\prod_{y \in T_t(\mathcal{R}_k(\Phi))} \mathbf{u}_{k+1,i,k}(y, x) \right) \right] \Lambda(dx) \\
&= g_{k,\Lambda}(t, \mathbf{H}_{i,k}(\mathbf{v}, x)) \tag{C.4}
\end{aligned}$$

if $i - 1 \in J_k$ and

$$\begin{aligned}
& \mathbb{E} \left[\left(\prod_{j=1}^k \left(\prod_{y \in T_t(\mathcal{Q}_j(\Phi))} v_j(y) \right) \right) \left(\prod_{y \in T_t(\mathcal{R}_k(\Phi))} v_{k+1}(y) \right) \Lambda_{i,t}(dx) \right] \\
&= \mathbb{E} \left[\left(\prod_{j=1}^k \left(\prod_{y \in T_t(\mathcal{Q}_j(\Phi))} v_j(y) \right) \right) \left(\prod_{y \in T_t(\mathcal{R}_k(\Phi))} v_{k+1}(y) \right) \right. \\
&\quad \left. \left(\prod_{y \in T_t(\mathcal{M}_{i-1}(\Phi))} (1 - h(x, y)) \right) \Lambda(dx) \right] \\
&= \mathbb{E} \left[\left(\prod_{j=1}^k \left(\prod_{y \in T_t(\mathcal{Q}_j(\Phi))} v_j(y) \right) \right) \left(\prod_{y \in T_t(\mathcal{R}_k(\Phi))} v_{k+1}(y) \right) \right. \\
&\quad \left. \left(\prod_{k \geq j \geq 1, i-1 \in I_j} \left(\prod_{y \in T_t(\mathcal{Q}_j(\Phi))} (1 - h(x, y)) \right) \right) \right] \Lambda(dx) \\
&= \mathbb{E} \left[\left(\prod_{j=1}^k \left(\prod_{y \in T_t(\mathcal{Q}_j(\Phi))} \mathbf{u}_{j,i,k}(y, x) \right) \right) \left(\prod_{y \in T_t(\mathcal{R}_k(\Phi))} \mathbf{u}_{k+1,i,k}(y, x) \right) \right] \Lambda(dx) \\
&= g_{k,\Lambda}(t, \mathbf{H}_{i,k}(\mathbf{v}, x)) \tag{C.5}
\end{aligned}$$

otherwise.

We conclude by substituting the above equalities to (C.2) and (C.3).

D Proof of Proposition 9

As there is no ambiguity, we drop the ∞ and Λ subscripts in this proof. By Proposition 13,

$$\frac{d}{ds} f(t, v e^{-s \mathbf{1}_B}) \Big|_{s=0} = - \int_B v(y) f_y(t, v) m(t, y) \Lambda(dy).$$

By Theorem 2,

$$f(t, v e^{-s \mathbf{1}_B}) = 1 - \int_0^t \int_{\mathbb{R}^2} f(\tau, H(v e^{-s \mathbf{1}_B}, x)) \left(1 - v(x) e^{-s \mathbf{1}_B(x)} \right) \Lambda(dx) d\tau.$$

By the same argument as in the proof of Proposition 8, we can change the order of integration and derivation in the above formula,

$$\begin{aligned}
& \int_B v(y) f_y(t, v) m(t, y) \Lambda(dx) \\
&= \frac{d}{ds} \left(\int_0^t \int_{\mathbb{R}^2} f(\tau, H(v e^{-s \mathbf{1}_B}, x)) \left(1 - v(x) e^{-s \mathbf{1}_B(x)} \right) \Lambda(dx) d\tau \right) \Big|_{s=0} \\
&= \int_0^t \int_{\mathbb{R}^2} \frac{d}{ds} \left(f(\tau, H(v e^{-s \mathbf{1}_B}, x)) \left(1 - v(x) e^{-s \mathbf{1}_B(x)} \right) \right) \Big|_{s=0} \Lambda(dx) d\tau.
\end{aligned}$$

Moreover,

$$\begin{aligned}
& \frac{d}{ds} \left(f(\tau, H(v e^{-s \mathbf{1}_B}, x)) \left(1 - v(x) e^{-s \mathbf{1}_B(x)} \right) \right) \Big|_{s=0} \\
&= \frac{d}{ds} f(\tau, H(v e^{-s \mathbf{1}_B}, x)) \Big|_{s=0} (1 - v(x)) + \mathbf{1}_B(x) v(x) f(\tau, H(v, x)).
\end{aligned}$$

By Proposition 13,

$$\begin{aligned}
\frac{d}{ds} f(\tau, H(v e^{-s \mathbf{1}_B}, x)) \Big|_{s=0} &= \frac{d}{ds} f(\tau, H(v, x) e^{-s \mathbf{1}_B}) \Big|_{s=0} \\
&= - \int_B f_y(\tau, H(v, x)) v(y) (1 - h(x, y)) m(\tau, y) \Lambda(dy)
\end{aligned}$$

for every x . Hence,

$$\begin{aligned}
& \int_B v(y) f_y(t, v) m(t, y) \Lambda(dx) \\
&= - \int_0^t \int_{\mathbb{R}^2} \int_B f_y(\tau, H(v, x)) v(y) (1 - h(x, y)) m(\tau, y) \Lambda(dy) \Lambda(dx) d\tau \\
&\quad + \int_0^t \int_B f(\tau, H(v, x)) v(x) \Lambda(dx) d\tau \\
&= - \int_0^t \int_{\mathbb{R}^2} \int_B f_y(\tau, H(v, x)) v(y) (1 - h(x, y)) m(\tau, y) \Lambda(dy) \Lambda(dx) d\tau \\
&\quad + \int_0^t \int_B f(\tau, H(v, y)) v(y) \Lambda(dy) d\tau \\
&= - \int_B \int_0^t \int_{\mathbb{R}^2} f_y(\tau, H(v, x)) v(y) (1 - h(x, y)) m(\tau, y) \Lambda(dx) d\tau \Lambda(dy) \\
&\quad + \int_B \int_0^t f(\tau, H(v, y)) v(y) d\tau \Lambda(dy).
\end{aligned}$$

As this is true for any bounded measurable set B such that $v(x) > 0$ for all x in B , we must have

$$f_y(t, v) = \frac{\int_0^t f(\tau, H(v, y)) d\tau}{m(t, y)} - \int_0^t \int_{\mathbb{R}^2} f_y(\tau, H(v, x)) (1 - v(x)) (1 - h(x, y)) \frac{m(\tau, y)}{m(t, y)} \Lambda(dx) d\tau$$

for Λ -almost every y such that $v(y) > 0$. For y such that $v(y) = 0$, by Proposition 14, for any bounded measurable set B not in the support of v ,

$$\frac{d}{ds} f(t, v + s\mathbf{1}_B) \Big|_{s=0} = \int_B f_y(t, v) m(t, y) \Lambda(dy).$$

Again, by Theorem 2,

$$\begin{aligned} & f(t, v + s\mathbf{1}_B) \\ &= 1 - \int_0^t \int_{\mathbb{R}^2} f(\tau, H(v + s\mathbf{1}_B, x)) (1 - v(x) - s\mathbf{1}_B(x)) \Lambda(dx) d\tau. \end{aligned}$$

By using the same arguments as above and by noting that

$$\begin{aligned} \frac{d}{ds} f(\tau, H(v + s\mathbf{1}_B, x)) \Big|_{s=0} &= \frac{d}{ds} f(\tau, H(v, x) + s\mathbf{1}_B(1 - h(\cdot, x))) \Big|_{s=0} \\ &= \int_B f_y(\tau, H(v, x)) (1 - h(x, y)) m(\tau, y) \Lambda(dy), \end{aligned}$$

we have

$$f_y(t, v) = \frac{\int_0^t f(\tau, H(v, y)) d\tau}{m(t, y)} - \int_0^t \int_{\mathbb{R}^2} f_y(\tau, H(v, x)) (1 - v(x)) (1 - h(x, y)) \frac{m(\tau, y)}{m(t, y)} \Lambda(dx) d\tau$$

for Λ -almost every x such that $v(x) = 0$.
